## (Automação de Processos Industriais)

### Discrete Event Systems

<http://users.isr.ist.utl.pt/~jag/courses/api1516/api1516.html>

Slides 2010/2011 Prof. Paulo Jorge Oliveira  
Rev. 2011-2015 Prof. José Gaspar

## Syllabus:

### **Chap. 5 – CAD/CAM and CNC [1 week]**

...

### **Chap. 6 – Discrete Event Systems [2 weeks]**

Discrete event systems modeling. Automata.

Petri Nets: state, dynamics, and modeling.

Extended and strict models. Subclasses of Petri nets.

...

### **Chap. 7 – Analysis of Discrete Event Systems [2 weeks]**

## Some pointers to Discrete Event Systems

History: <http://prosys.changwon.ac.kr/docs/petrinet/1.htm>

Tutorial: <http://vita.bu.edu/cgc/MIDEDS/>  
<http://www.daimi.au.dk/PetriNets/>

Analyzers,  
and  
Simulators: <http://www.ppgia.pucpr.br/~maziero/petri/arp.html> (in Portuguese)  
<http://wiki.daimi.au.dk:8000/cpntools/cpntools.wiki>  
<http://www.informatik.hu-berlin.de/top/pnk/download.html>

Bibliography:

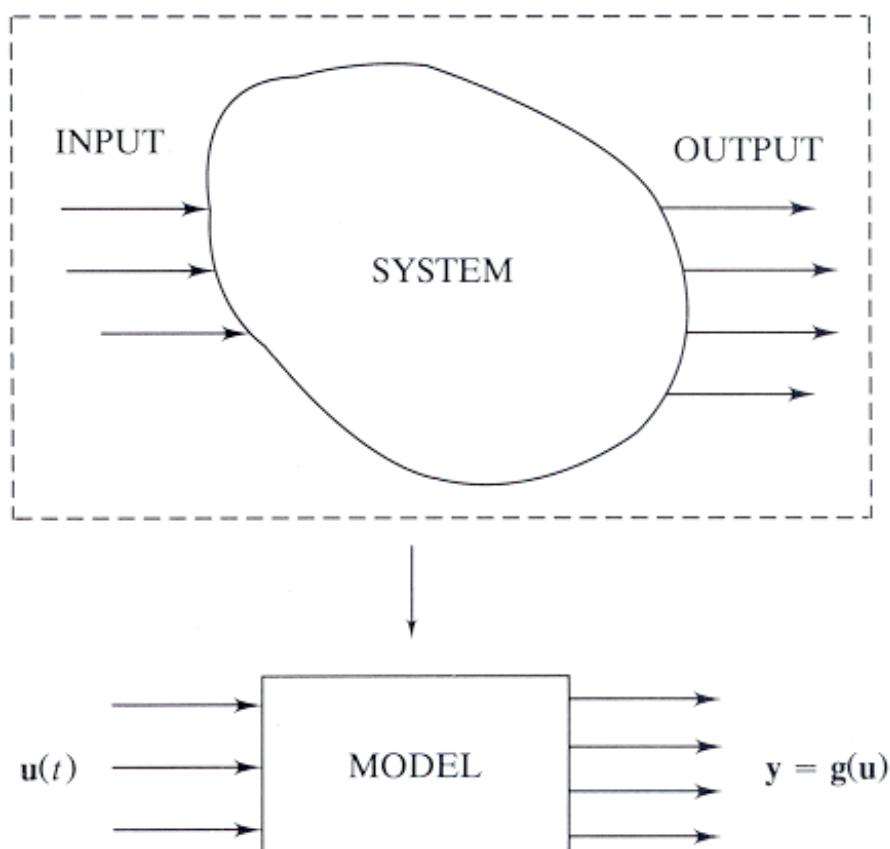

Figure 1.1. Simple modeling process.

Generic characterization of systems resorting to input / output relations

State equations:

$$\begin{cases} \dot{x}(t) = f(x(t), u(t), t) \\ y(t) = g(x(t), u(t), t) \end{cases}$$

in continuous time (or in discrete time)

Examples?

Control: Open loop vs closed-loop ( $\Leftrightarrow$  the use of feedback)

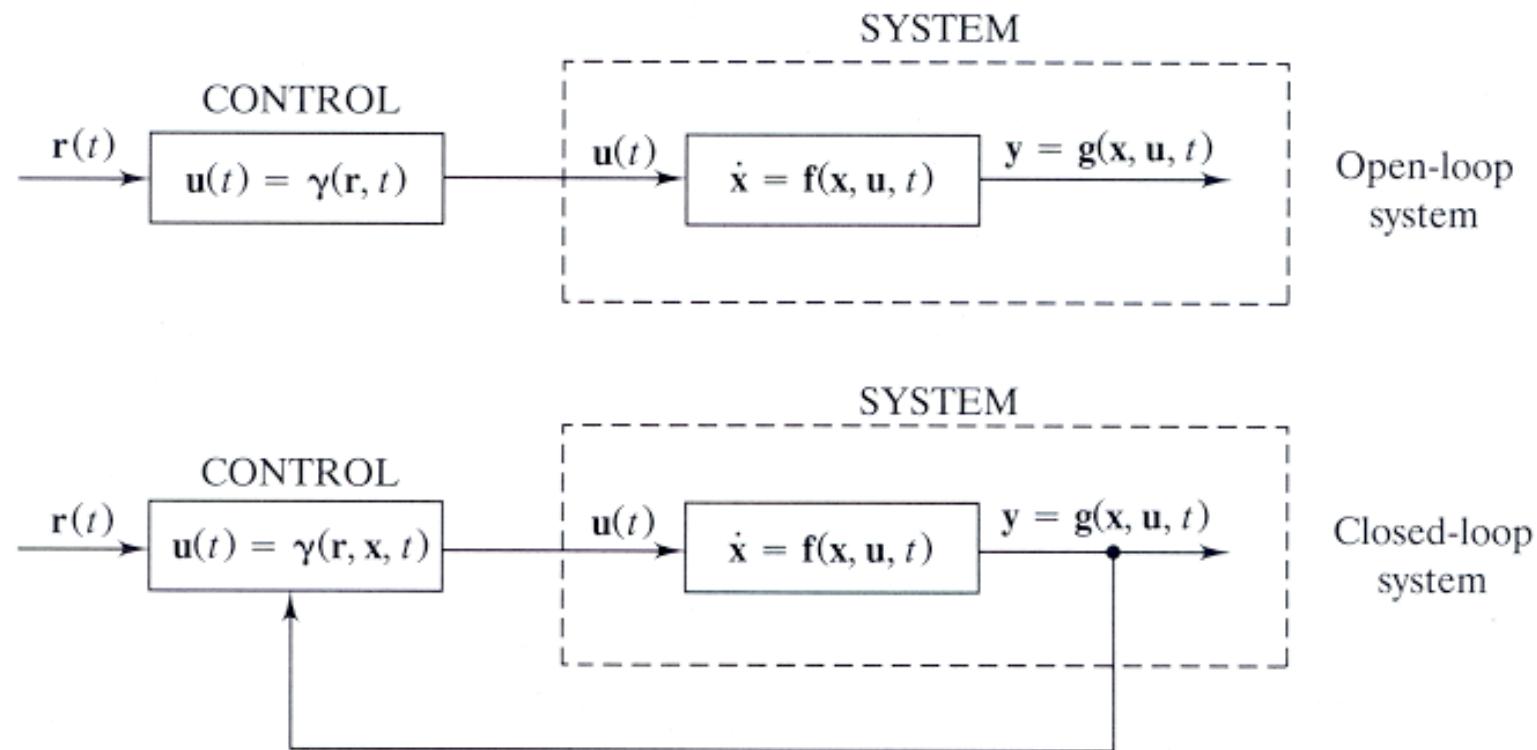

Figure 1.17. Open-loop and closed-loop systems.

*Advantages of feedback?*

*(to revisit during DES supervision study)*

## Example of closed-loop with feedback

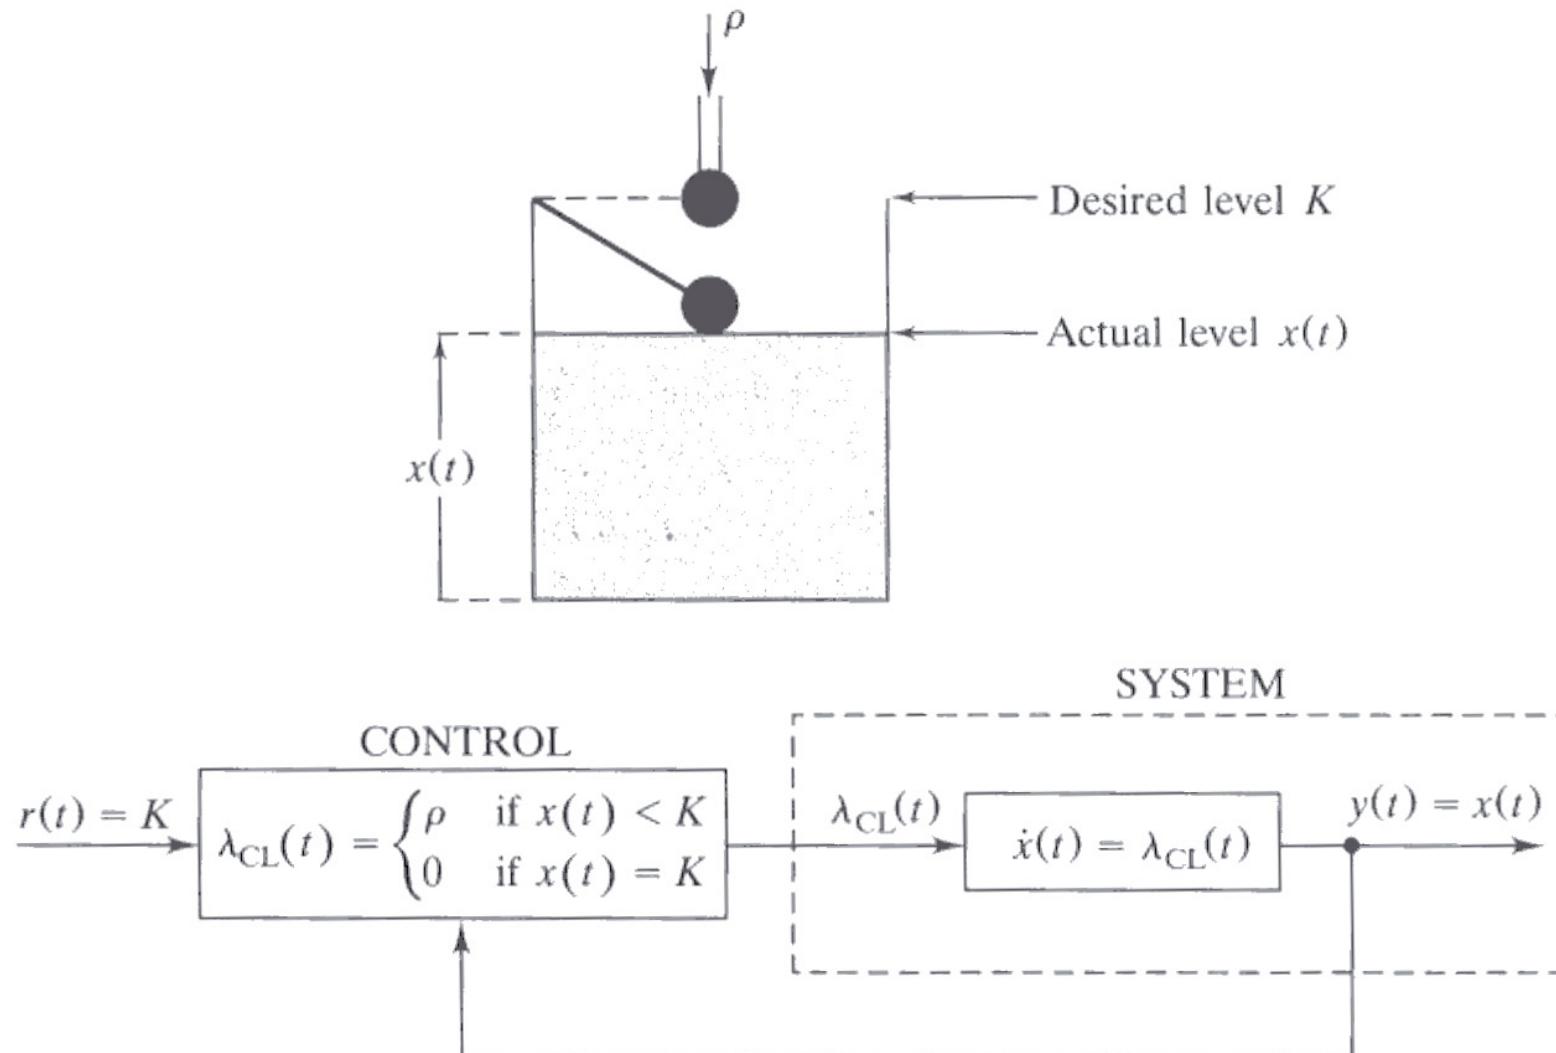

Figure 1.18. Flow system of Example 1.11 and closed-loop control model.

## Discrete Event Systems: Examples

Set of events:

$$E = \{N, S, E, W\}$$

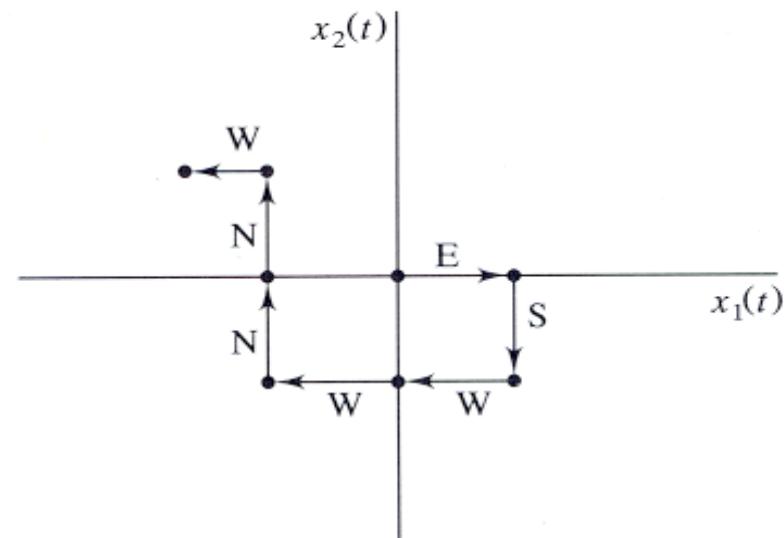

Figure 1.20. Random walk on a plane for Example 1.12.

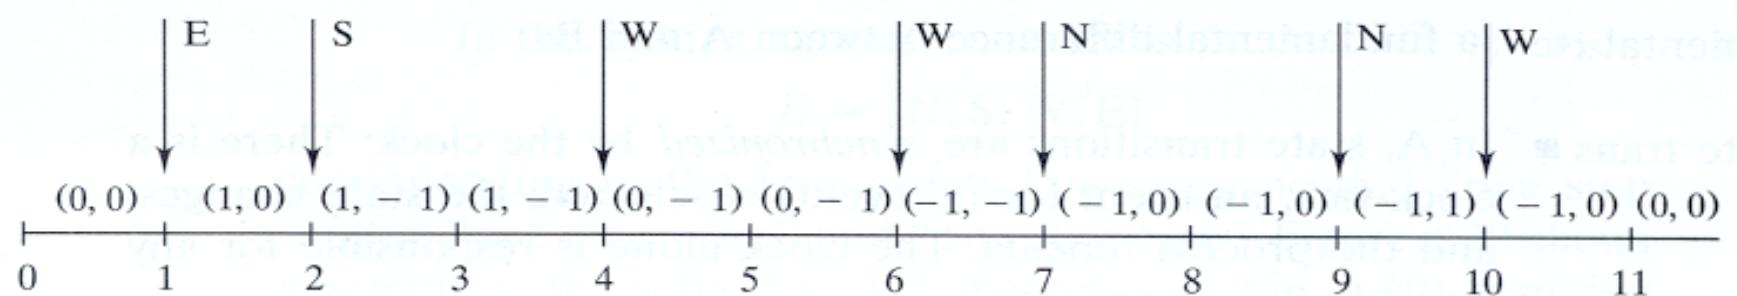

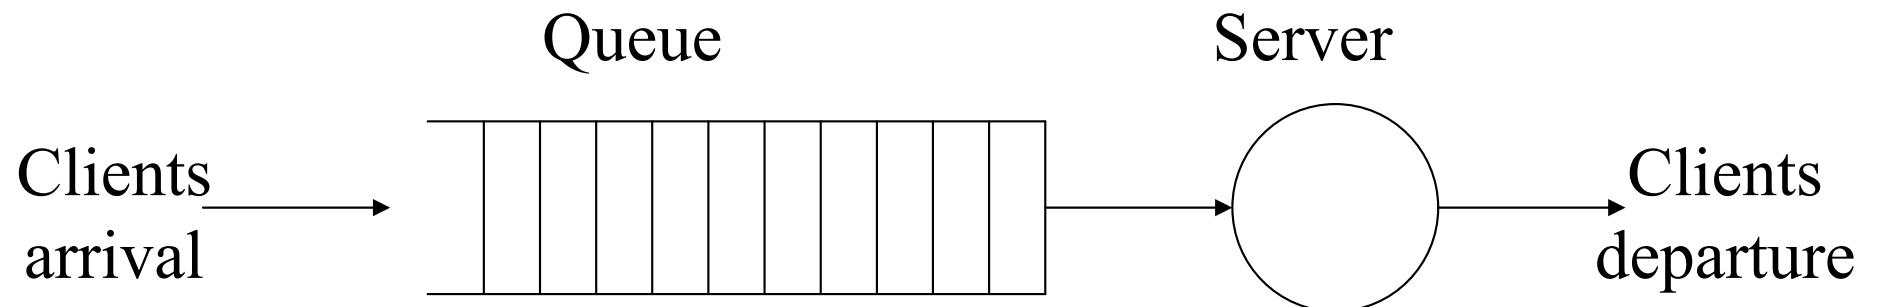

Figure 1.21. Event-driven random walk on a plane.

## Discrete Event Systems: Examples

Queueing systems

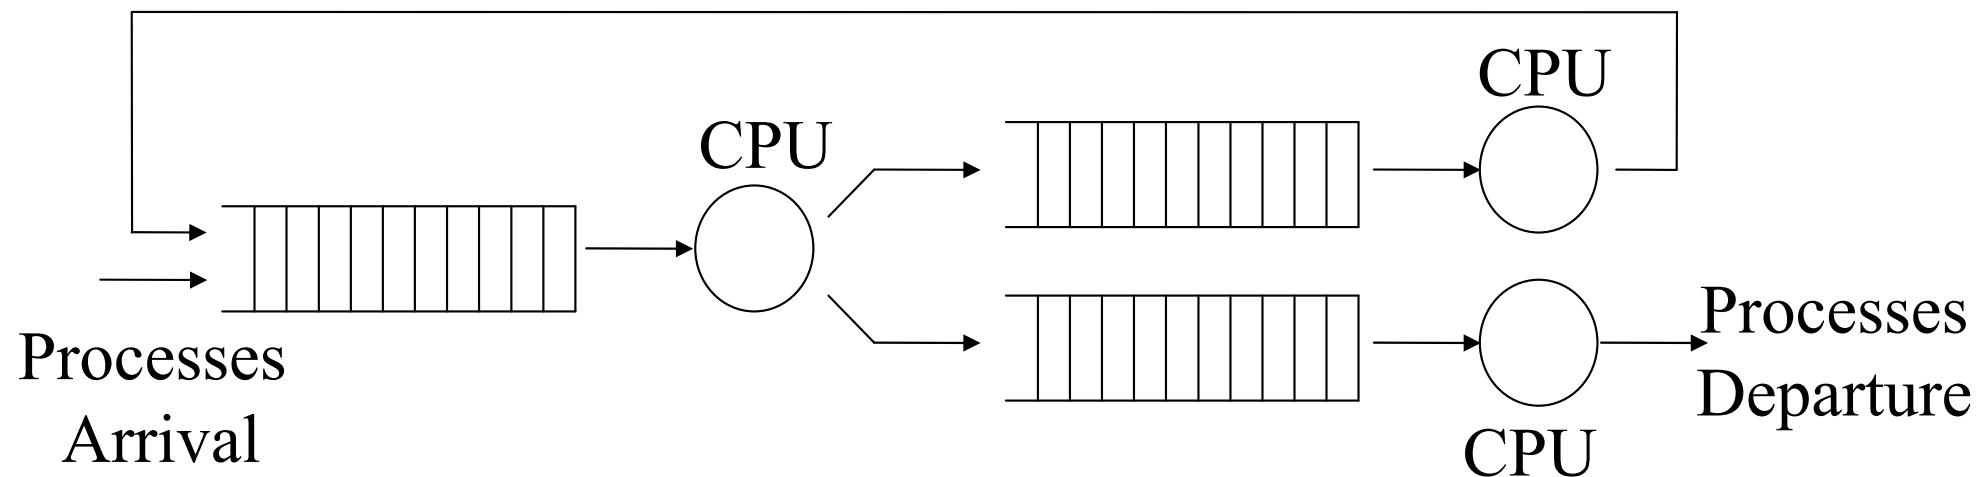

Set of events:

$$E = \{\text{arrival, departure}\}$$

## Discrete Event Systems: Examples

### Computational Systems

## Characteristics of systems with continuous variables

1. State space is continuous
2. The state transition mechanism is *time-driven*

## Characteristics of systems with discrete events

1. State space is discrete
2. The state transition mechanism is *event-driven*

***Intrinsic characteristic of discrete events systems: Polling is avoided!***

# Taxonomy of Systems

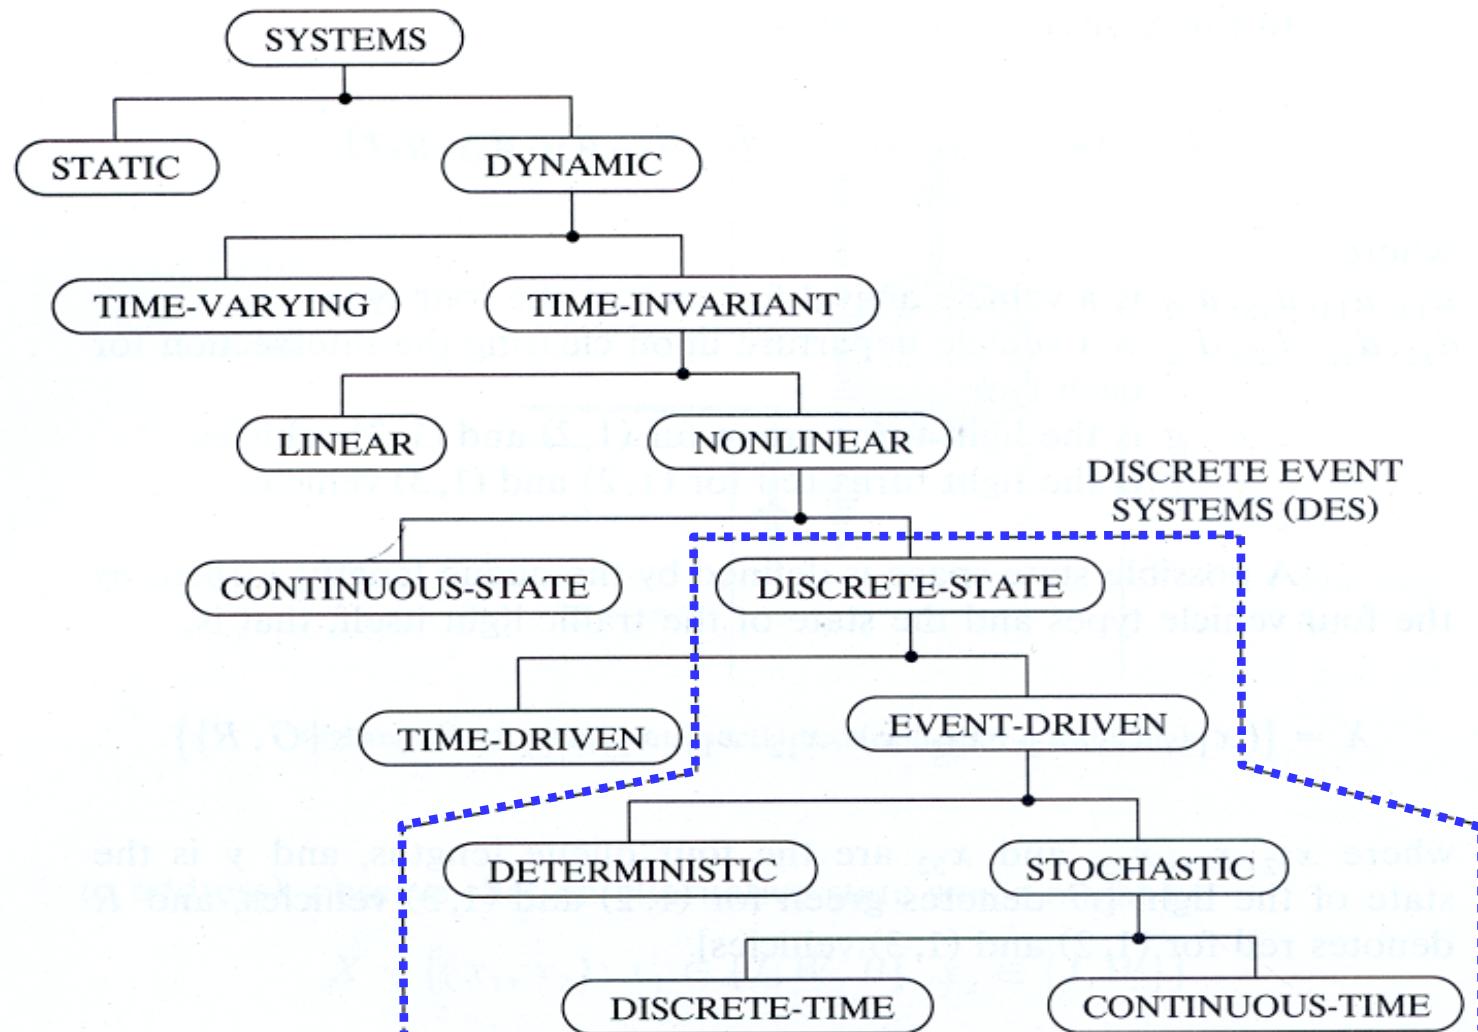

Figure 1.29. Major system classifications.

# Levels of abstraction in the study of Discrete Event Systems

*Language of a “chocolate selling machine”:*

- (i) Waiting for a coin.
- (ii) *Received 1 euro coin.*  
*Chocolate A given. Go to (i).*
- (iii) *Received 2 euro coin.*  
*Chocolate B given. Go to (i).*

4 sensors:

*Received 1 euro coin,*  
*Received 2 euro coin,*  
*Chocolate A given,*  
*Chocolate B given.*

*Languages*

*Timed languages*

*Stochastic timed languages*

# Systems Theory Objectives

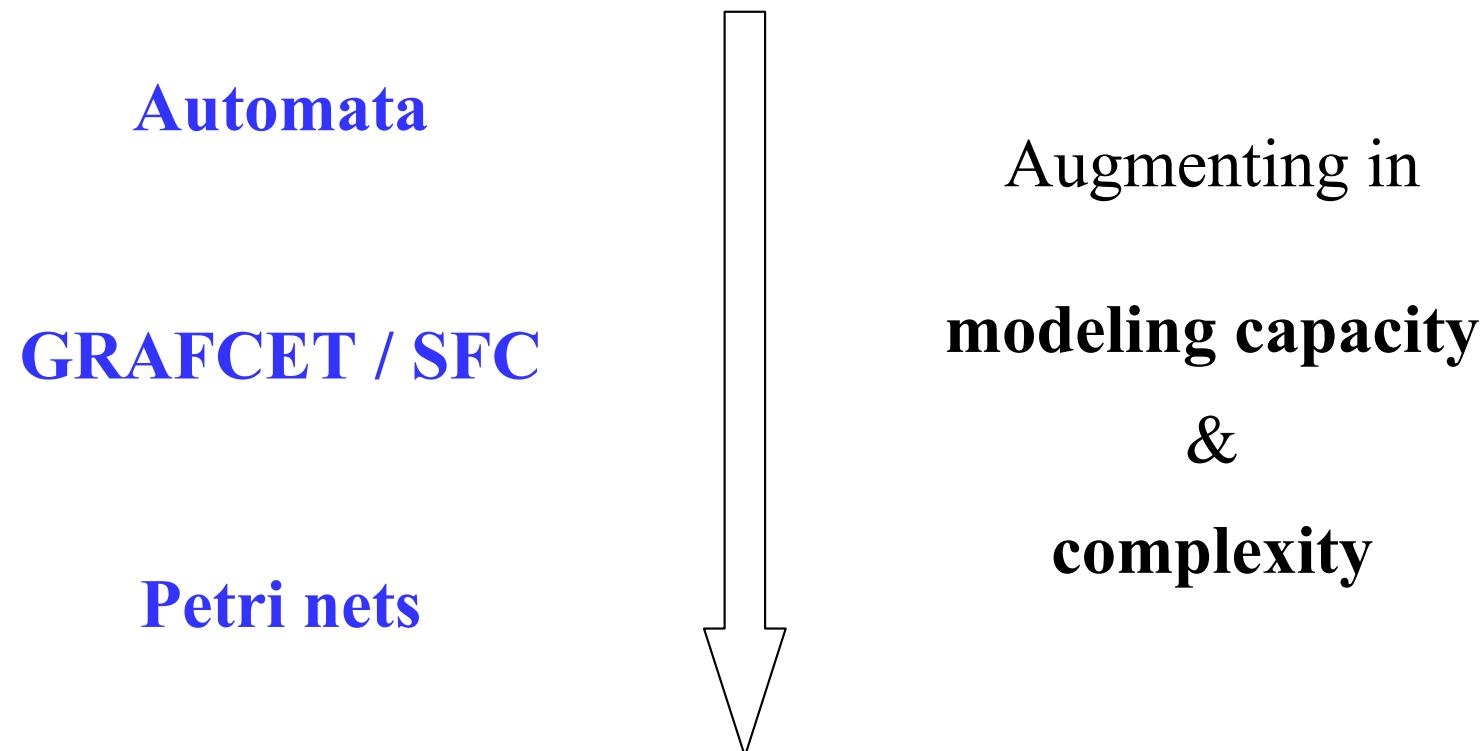

- Modeling and Analysis
- *Design* and synthesis
- Control / Supervision
- Performance assessment and robustness
- Optimization

# Applications of Discrete Event Systems

- Queueing systems
- Operating systems and computers
- Telecommunications networks
- Distributed databases
- Automation

# Discrete Event Systems

Typical modeling methodologies

## Automata Theory and Languages

Genesis of computation theory

**Definition:** A language  $L$ , defined over the alphabet  $E$  is a set of *strings* of finite length with events from  $E$ .

Examples:  $E = \{\alpha, \beta, \gamma\}$

$L_1 = \{\epsilon, \alpha\alpha, \alpha\beta, \gamma\beta\alpha\}$ , where  $\epsilon$  is the null/empty string

$L_2 = \{\text{all } strings \text{ of length 3}\}$

How to build a machine that “talks” a given language?

or

What language “talks” a system?

## Operations / Properties of languages

$E^*$  = **Kleene-closure** of  $E$ : set of all strings of finite length  
of  $E$ , including the null element  $\epsilon$ .

**Concatenation** of  $L_a$  and  $L_b$ :

$$L_a L_b := \left\{ s \in E^* : s = s_a s_b, s_a \in L_a, s_b \in L_b \right\}$$

**Prefix-closure** of  $L \subseteq E^*$ :

$$\bar{L} := \left\{ s \in E^* : \exists_{t \in E^*} st \in L \right\}$$

## Operations / Properties of languages

### Example 2.1 (Operations on languages)

Let  $E = \{a, b, g\}$ , and consider the two languages  $L_1 = \{\varepsilon, a, abb\}$  and  $L_4 = \{g\}$ . Neither  $L_1$  nor  $L_4$  are prefix-closed, since  $ab \notin L_1$  and  $\varepsilon \notin L_4$ . Then:

$$\begin{aligned}L_1 L_4 &= \{g, ag, abbg\} \\ \overline{L_1} &= \{\varepsilon, a, ab, abb\} \\ \overline{L_4} &= \{\varepsilon, g\} \\ L_1 \overline{L_4} &= \{\varepsilon, a, abb, g, ag, abbg\} \\ L_4^* &= \{\varepsilon, g, gg, ggg, \dots\} \\ L_1^* &= \{\varepsilon, a, abb, aa, aabb, abba, abbabb, \dots\}\end{aligned}$$

[Cassandras99]

## Automata Theory and Languages

**Motivation:** An **automaton** is a device capable of representing a language according to some rules.

**Definition:** A deterministic **automaton** is a 5-tuple

$$(E, X, f, x_0, F)$$

where:

E	- finite alphabet (or possible events)	
X	- finite set of states	
f	- state transition function	$f: X \times E \rightarrow X$
$x_0$	- initial state	$x_0 \subset X$
F	- set of final states or marked states	$F \subset E$ [Cassandras93]

Word of caution: the word “state” is used here to mean “step” (Grafcet) or “place” (Petri Nets)

Example 1 of an automaton:

$$(E, X, f, x_0, F)$$

$$E = \{ \alpha, \beta, \gamma \}$$

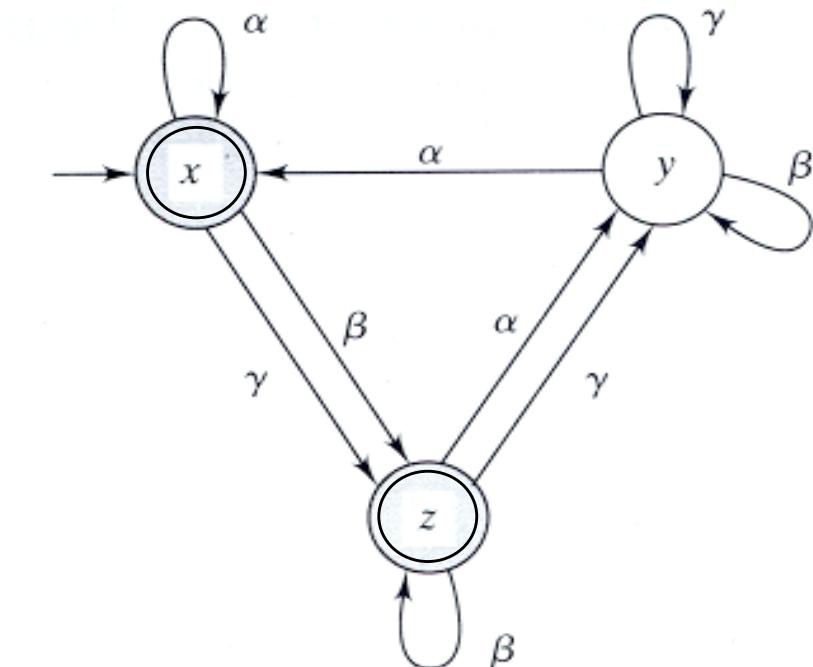

$$X = \{x, y, z\}$$

$$x_0 = x$$

$$F = \{x, z\}$$

$$\begin{aligned} f(x, \alpha) &= x \\ f(y, \alpha) &= x \\ f(z, \alpha) &= y \end{aligned}$$

$$\begin{aligned} f(x, \beta) &= z \\ f(y, \beta) &= y \\ f(z, \beta) &= z \end{aligned}$$

**Figure 2.1.** State transition diagram for Example 2.3.

$$\begin{aligned} f(x, \gamma) &= z \\ f(y, \gamma) &= y \\ f(z, \gamma) &= y \end{aligned}$$

## Example 2 of a stochastic automaton

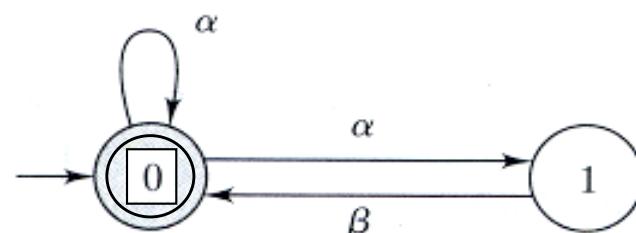

$$(E, X, f, x_0, F)$$

$$E = \{\alpha, \beta\}$$

$$X = \{0, 1\}$$

$$x_0 = 0$$

$$F = \{0\}$$

**Figure 2.4.** State transition diagram for the nondeterministic automaton of Example 2.7.

$$f(0, \alpha) = \{0, 1\} \quad f(0, \beta) = \{\}$$

$$f(1, \alpha) = \{\} \quad f(1, \beta) = 0$$

Given an automaton

$$G = (E, X, f, x_0, F)$$

the **Generated Language** is defined as

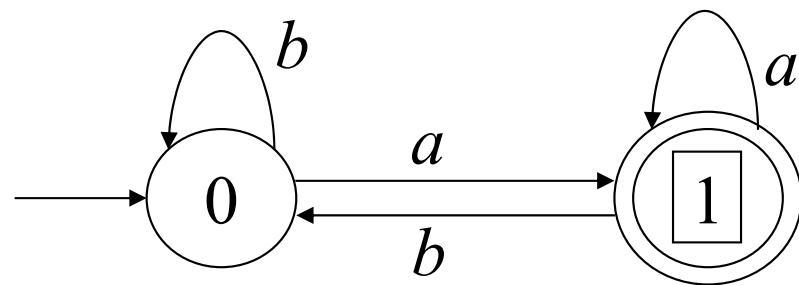

$$L(G) := \{s \in E^* : f(x_0, s) \text{ is defined}\}$$

*Note: if  $f$  is always defined then  $L(G) = E^*$*

and the **Marked Language** is defined as

$$L_m(G) := \{s \in E^* : f(x_0, s) \in F\}$$

Example 3: marked language of an automaton

$$L(G) := \{ \varepsilon, a, b, aa, ab, ba, bb, aaa, aab, baa, \dots \}$$

$$L_m(G) := \{ a, aa, ba, aaa, baa, bba, \dots \}$$

Concluding, in this example  $L_m(G)$  means all strings with events  $a$  and  $b$ , ended by event  $a$ .

Automata equivalence:

The automata  $G_1$  e  $G_2$  are equivalent if

$$L(G_1) = L(G_2)$$

and

$$L_m(G_1) = L_m(G_2)$$

## Example 4: two equivalent automata

Objective: To validate a sequence of events

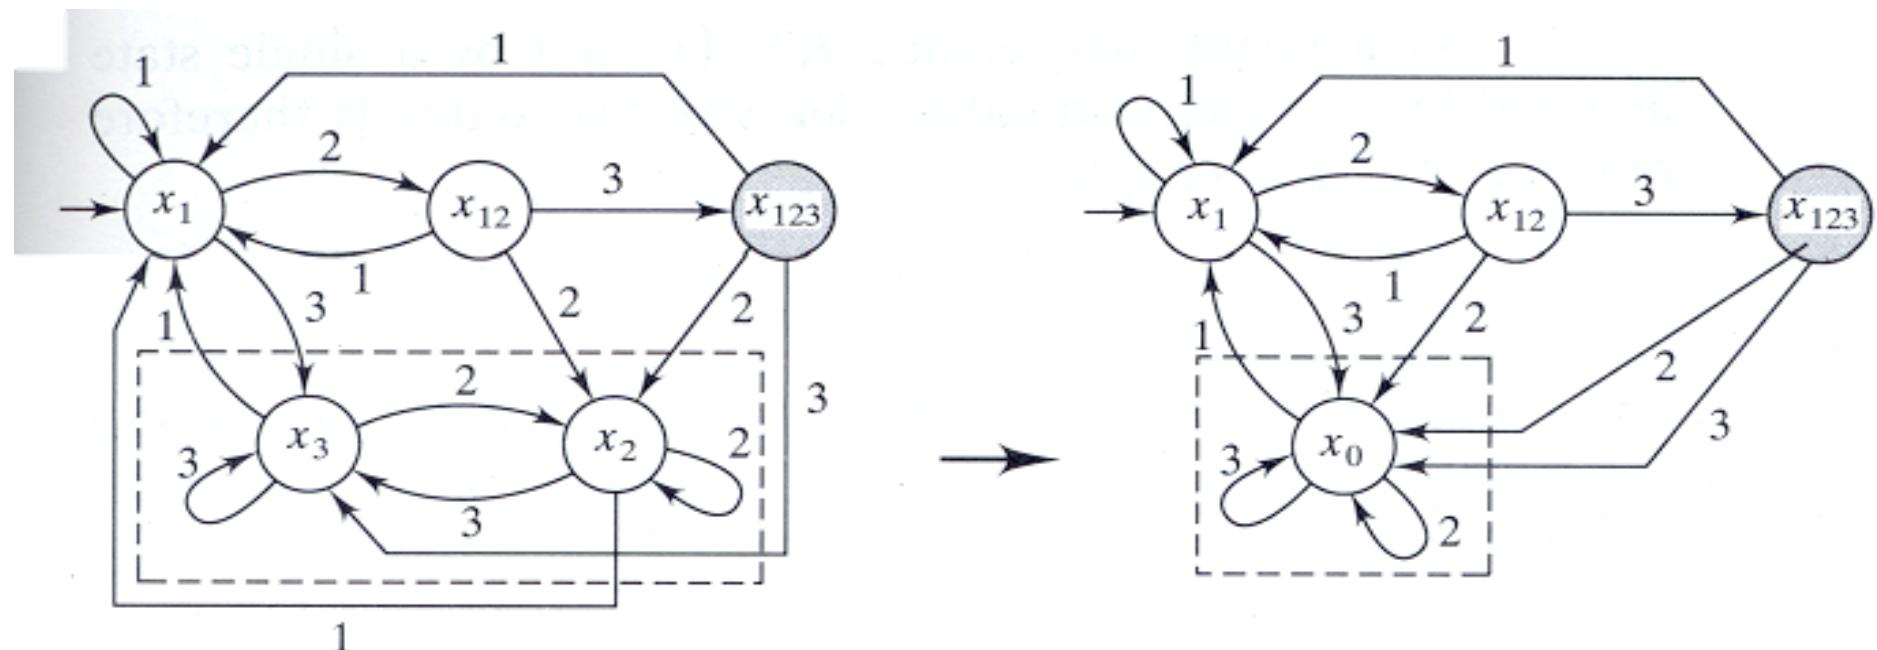

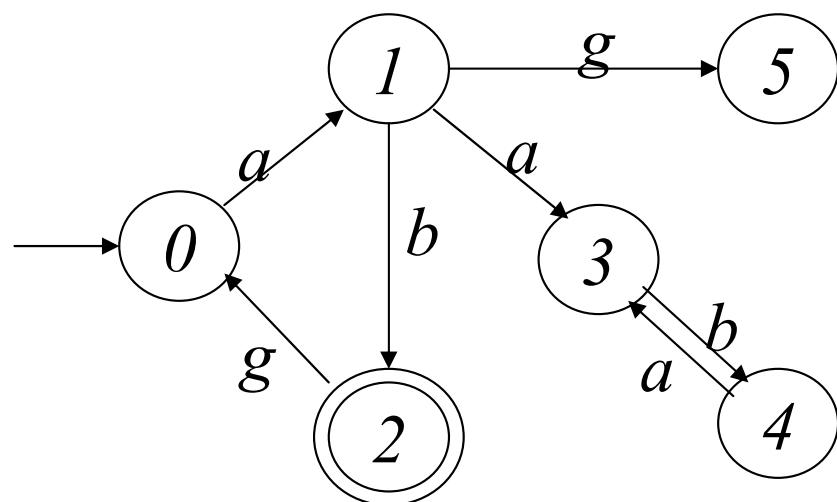

Figure 2.6. State transition diagrams for digit sequence detector in Example 2.9.

## Deadlocks (*inter-blocagem*)

Example 5:

The state 5 is a *deadlock*.

The states 3 and 4 constitute a *livelock*.

How to find  
the *deadlocks* and  
the *livelocks*?

*Need methodologies  
for the analysis  
of  
Discrete Event Systems*

Deadlock:

in general the following relations are verified

$$L_m(G) \subseteq \overline{L}_m(G) \subseteq L(G)$$

An automaton G has a deadlock if

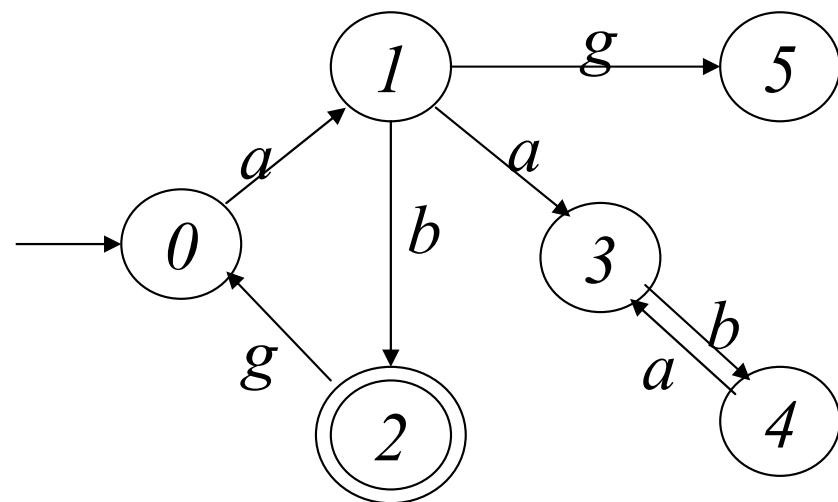

$$\overline{L}_m(G) \subset L(G)$$

and is not blocked when

$$\overline{L}_m(G) = L(G)$$

Deadlock:

Example:

$$L_m(G) = \{ab, abgab, abgabgb, \dots\}$$

$$L(G) = \left\{ \varepsilon, a, ab, ag, aa, aab, abg, aaba, abga, \dots \right\}$$

$$(L_m(G) \subset L(G))$$

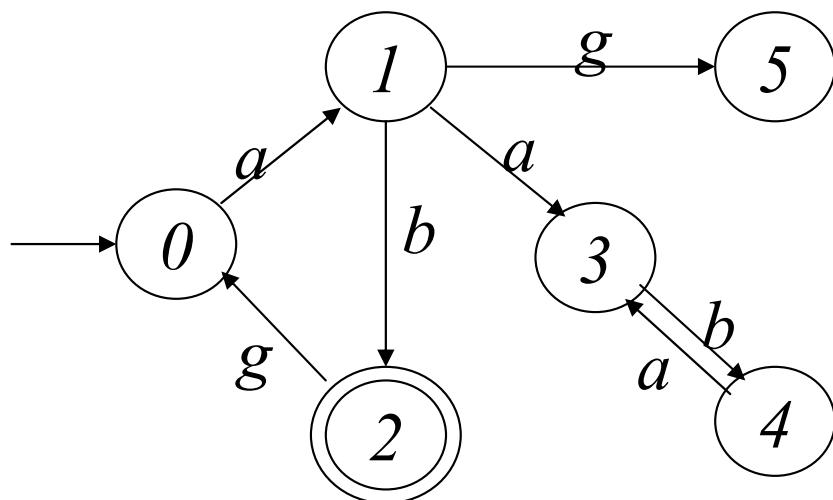

The state 5 is a *deadlock*.

The states 3 and 4  
constitute a *livelock*.

$$\overline{L}_m(G) \neq L(G)$$

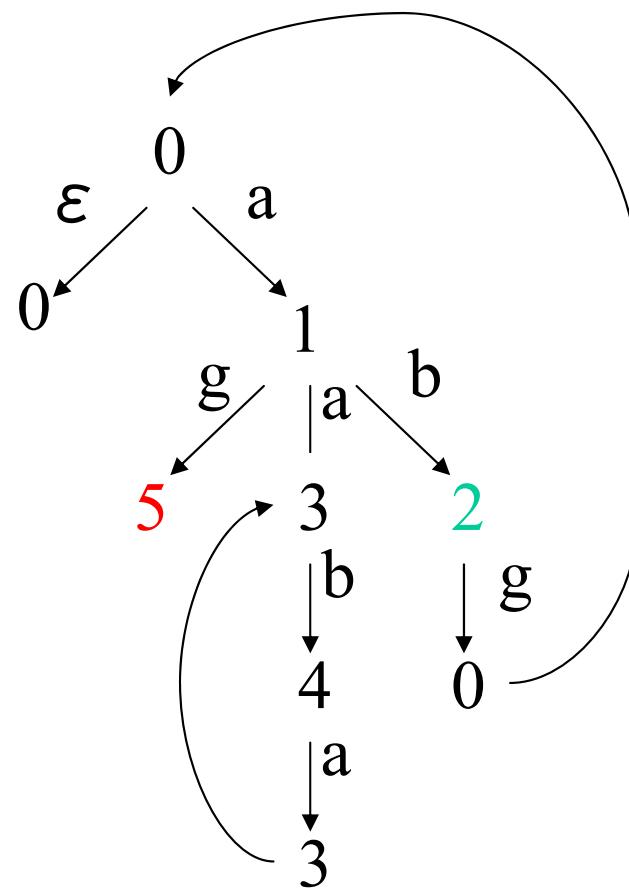

Alternative way to detect deadlocks:

Example:

The state 5 is a *deadlock*.

The states 3 and 4  
constitute a *livelock*.

## Timed Discrete Event Systems

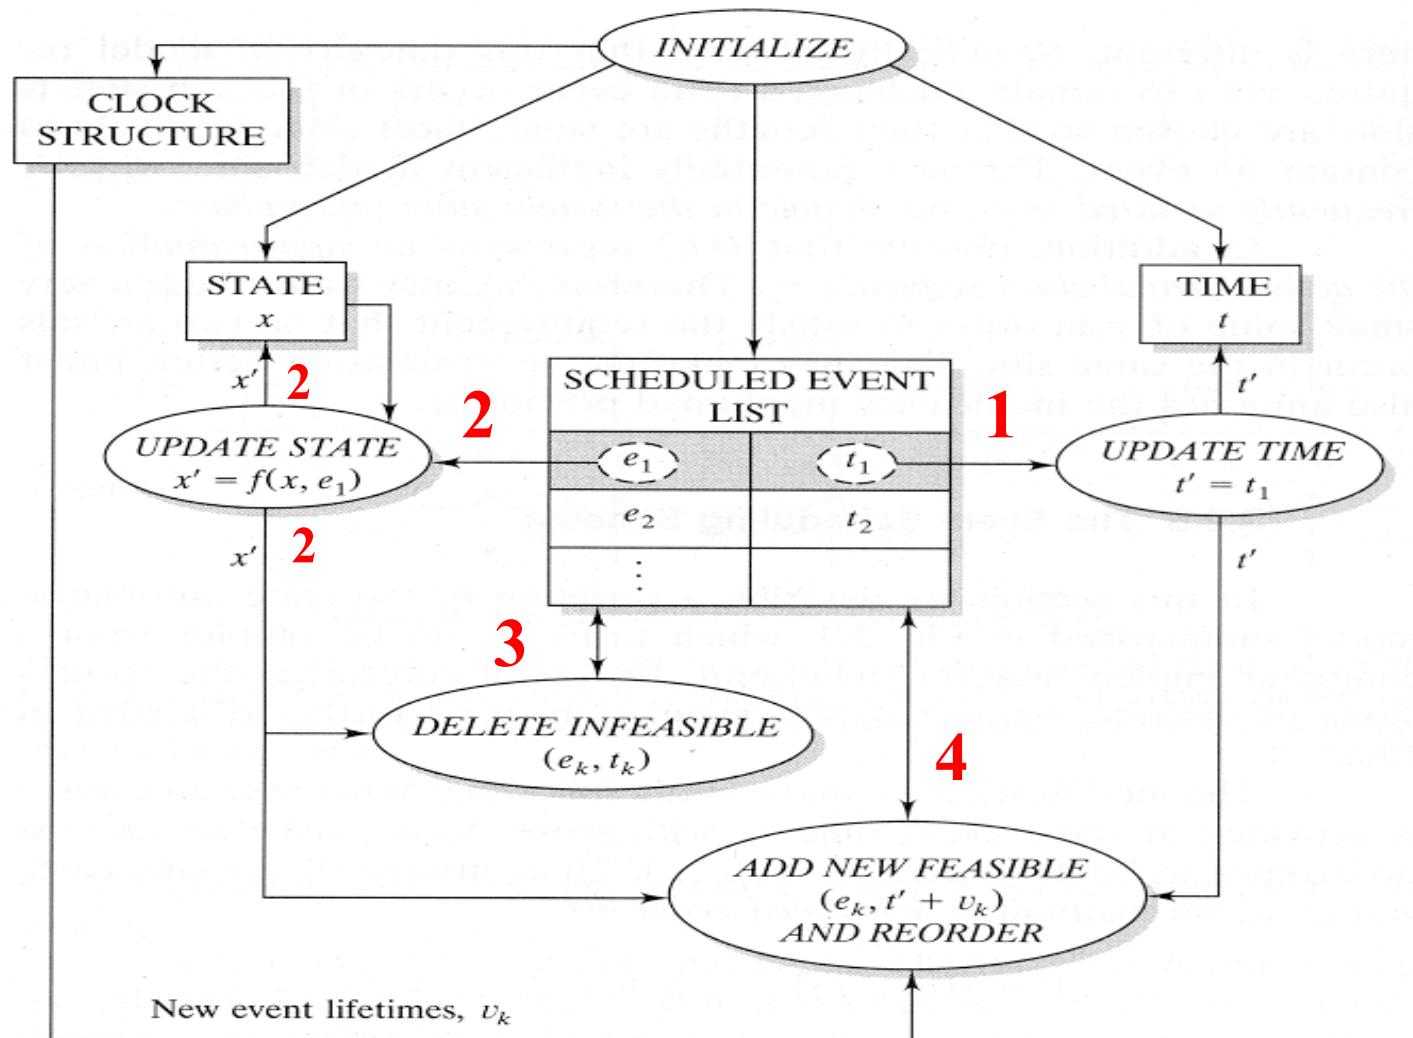

Figure 3.10. The event scheduling scheme.

## Examples of Automata Classes and Applications

Automaton Class	Recognizable language	Applications
Finite state machine (FSM), e.g. Moore machines or Mealy machines	Regular languages	Text processing, compilers, and hardware design
Pushdown automaton (PDA)	Context-free languages	Programming languages, artificial intelligence, (originally) study of the human languages
Turing machine (nondeterministic, deterministic, multitape, ...)	Recursively enumerable languages	Theory, complexity

## Petri nets

Developed by Carl Adam Petri in his PhD thesis in 1962.

**Definition:** A marked Petri net is a *5-tuple*

$$(P, T, A, w, x_0)$$

where:

$P$	- set of places	
$T$	- set of transitions	
$A$	- set of arcs	$A \subseteq (P \times T) \cup (T \times P)$
$w$	- weight function	$w: A \rightarrow N$
$x_0$	- initial marking	$x_0 : P \rightarrow N$ [Cassandras93]

## Example of a Petri net

$(P, T, A, w, x_0)$

$P = \{p_1, p_2, p_3, p_4, p_5\}$

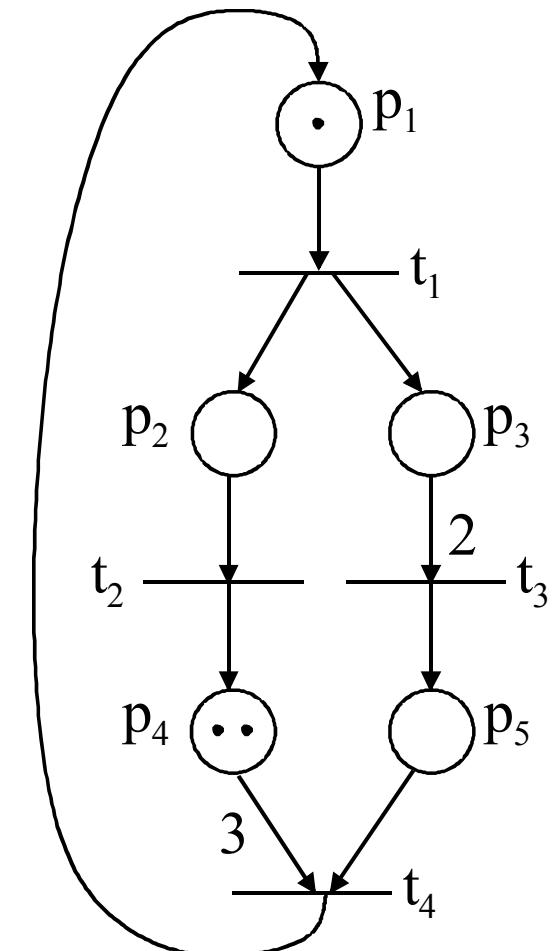

$T = \{t_1, t_2, t_3, t_4\}$

$A = \{(p_1, t_1), (t_1, p_2), (t_1, p_3), (p_2, t_2), (p_3, t_3),$   
 $(t_2, p_4), (t_3, p_5), (p_4, t_4), (p_5, t_4), (t_4, p_1)\}$

$w(p_1, t_1) = 1, w(t_1, p_2) = 1, w(t_1, p_3) = 1, w(p_2, t_2) = 1$   
 $w(p_3, t_3) = 2, w(t_2, p_4) = 1, w(t_3, p_5) = 1, w(p_4, t_4) = 3$   
 $w(p_5, t_4) = 1, w(t_4, p_1) = 1$

$x_0 = \{1, 0, 0, 2, 0\}$

## Petri net graph

## Petri nets

Rules to follow (mandatory):

- **Arcs** (directed connections)  
connect **places** to **transitions** and  
connect **transitions** to **places**
- A **transition** can have no **places** directly as inputs (source),  
*i.e. must exist arcs between transitions and places*
- A **transition** can have no **places** directly as outputs (sink),  
*i.e. must exist arcs between transitions and places*
- The same happens with the input and output **transitions** for **places**

## Alternative definition of a Petri net

A marked Petri net is a *5-tuple*

$$(P, T, I, O, \mu_0)$$

where:

<b>P</b>	- set of places	
<b>T</b>	- set of transitions	
<b>I</b>	- transition input function	$I : T \rightarrow P^\infty$
<b>O</b>	- transition output function	$O : T \rightarrow P^\infty$
$\mu_0$	- initial marking	$\mu_0 : P \rightarrow N$

[Peterson81]

Note:  $P^\infty$  = bag of places (is more general than a set of places)

## Example of a Petri net and its graphical representation

Alternative definition

$$(P, T, I, O, \mu_0)$$

$$P = \{p_1, p_2, p_3, p_4, p_5\}$$

$$T = \{t_1, t_2, t_3, t_4\}$$

$$I(t_1) = \{p_1\}$$

$$O(t_1) = \{p_2, p_3\}$$

$$I(t_2) = \{p_2\}$$

$$O(t_2) = \{p_4\}$$

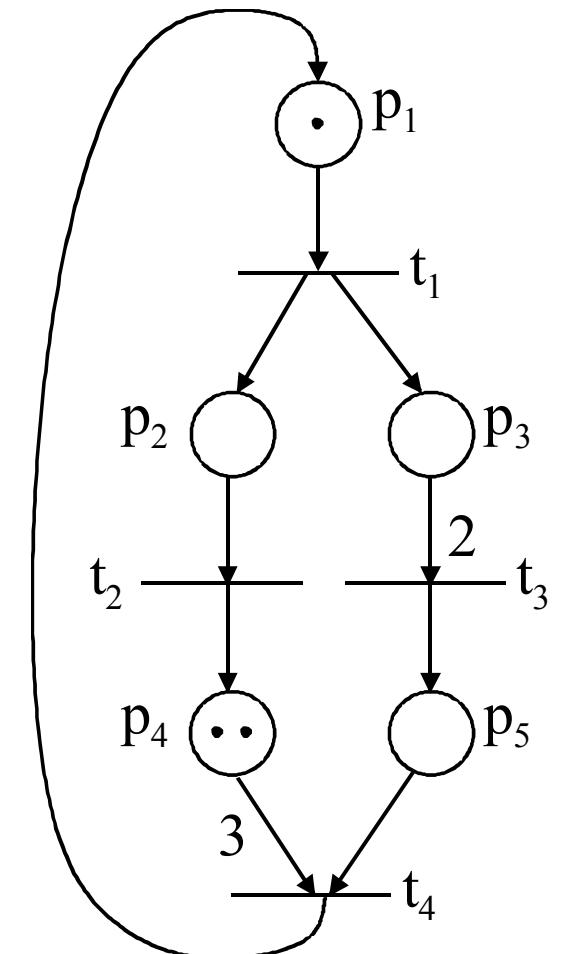

$$I(t_3) = \{p_3, p_3\}$$

$$O(t_3) = \{p_5\}$$

$$I(t_4) = \{p_4, p_4, p_4, p_5\}$$

$$O(t_4) = \{p_1\}$$

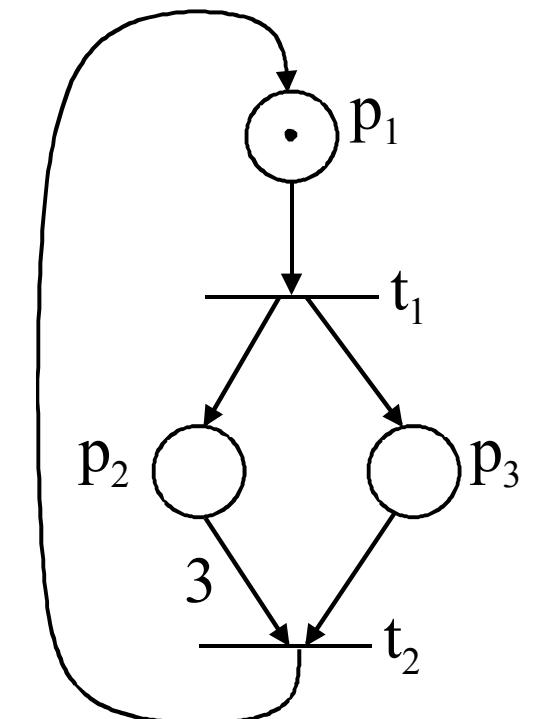

$$\mu_0 = \{1, 0, 0, 2, 0\}$$

## Petri nets

The **state** of a Petri net is characterized by the marking of all places.

The set of all possible markings of a Petri net corresponds to its **state space**.

How does the state of a Petri net evolve?

## Execution Rules for Petri Nets (Dynamics of Petri nets)

A transition  $t_j \in T$  is **enabled** if:

$$\forall p_i \in P: \quad \mu(p_i) \geq \#(p_i, I(t_j))$$

A transition  $t_j \in T$  may **fire** whenever enabled, resulting in a new marking given by:

$$\mu'(p_i) = \mu(p_i) - \#(p_i, I(t_j)) + \#(p_i, O(t_j))$$

$\#(p_i, I(t_j))$  = multiplicity of the arc from  $p_i$  to  $t_j$   
 $\#(p_i, O(t_j))$  = multiplicity of the arc from  $t_j$  to  $p_i$

[Peterson81 §2.3]

# Execution Rules for Petri Nets

## (Dynamics of Petri nets)

$$\#(p_i, I(t_j)) = 0$$

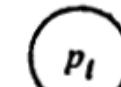

$$\#(p_i, O(t_j)) = 0$$

$$\#(p_i, O(t_j)) = 1$$

$$\#(p_i, I(t_j)) = 1$$

$$\mu'(p_i) = \mu(p_i)$$

$$\mu'(p_i) = \mu(p_i) + 1$$

$$\mu'(p_i) = \mu(p_i) - 1$$

$$\mu'(p_i) = \mu(p_i) - 1 + 1$$

$$\mu'(p_i) = \mu(p_i) - \#(p_i, I(t_j)) + \#(p_i, O(t_j))$$

## Petri nets

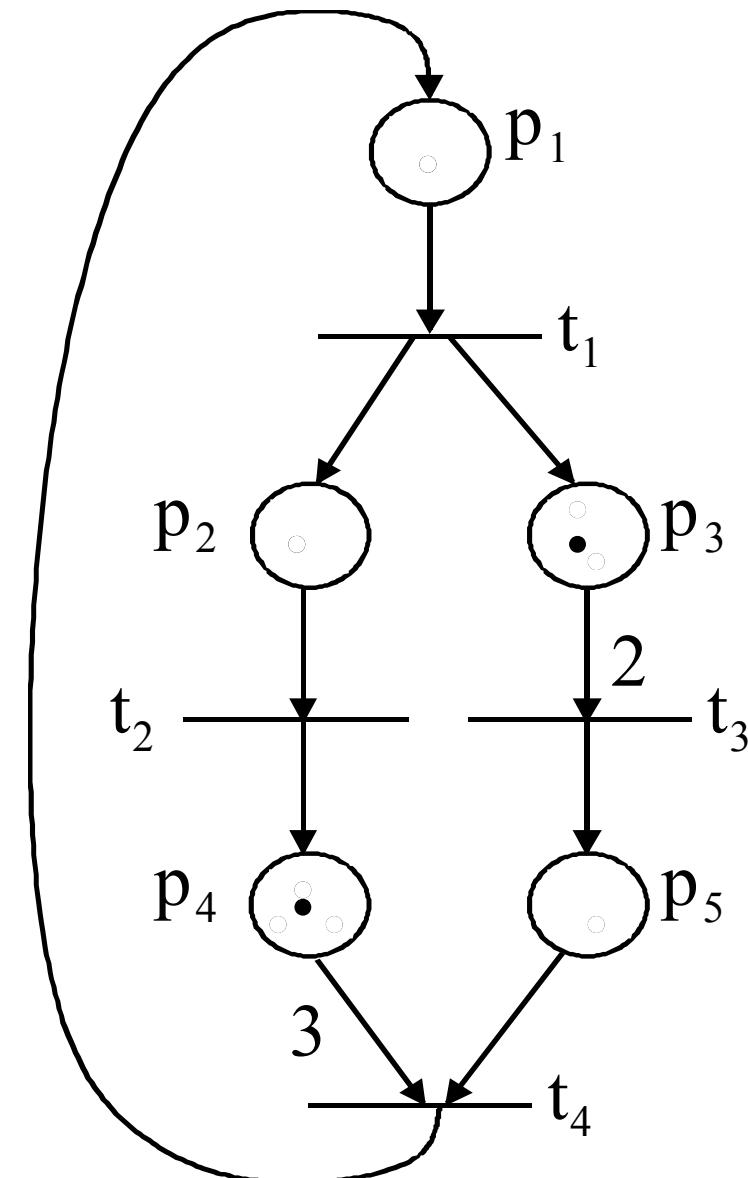

Example of evolution of a Petri net

Initial marking:

$$\mu_0 = \{1, 0, 1, 2, 0\}$$

This discrete event system can not change state.

It is in a *deadlock!*

## Petri nets: Conditions and Events (Places and Transitions)

Example: Machine waits until an order appears and then machines the ordered part and sends it out for delivery.

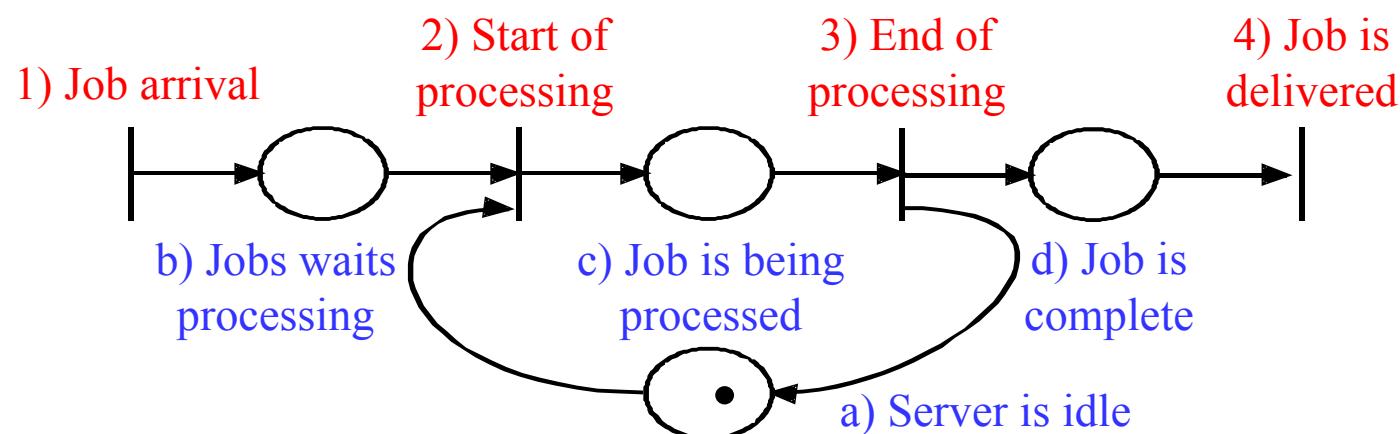

Conditions:

- a) The server is idle.
- b) A job arrives and waits to be processed
- c) The server is processing the job
- d) The job is complete

Events

- 1) Job arrival
- 2) Server starts processing
- 3) Server finishes processing
- 4) The job is delivered

Event	Pre-conditions	Post-conditions
1	-	b
2	a, b	c
3	c	d, a
4	d	-

# Discrete Event Systems

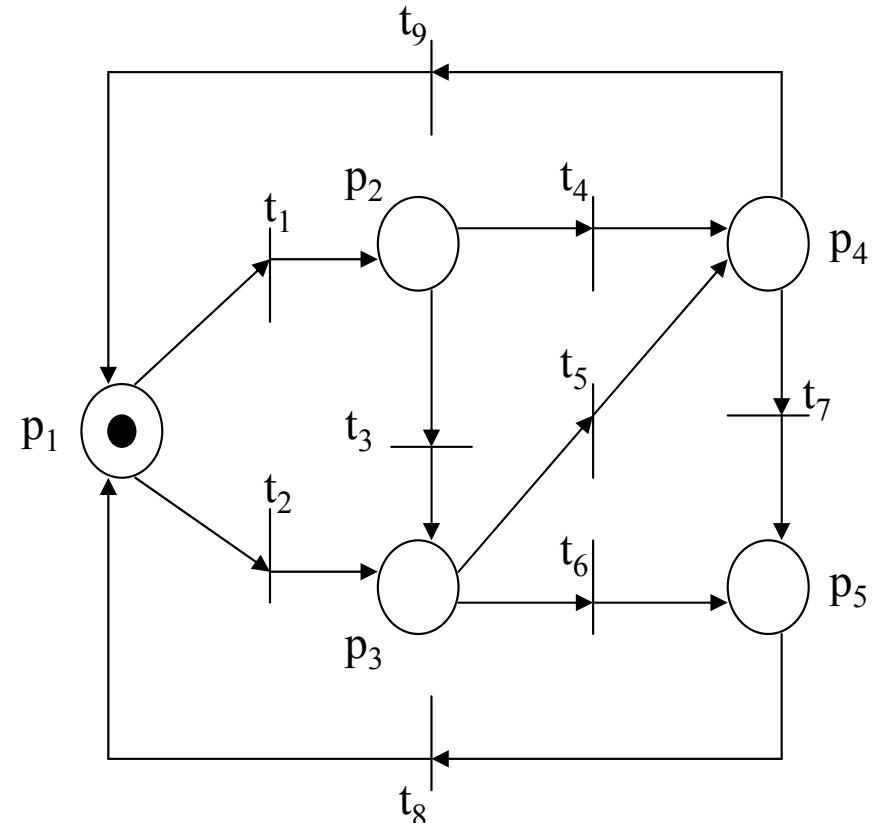

## Example of a simple automation system modeled using PNs

An automatic soda selling machine accepts

50c and \$1 coins and sells 2 types of products:

SODA A, that costs \$1.50 and SODA B, that costs \$2.00.

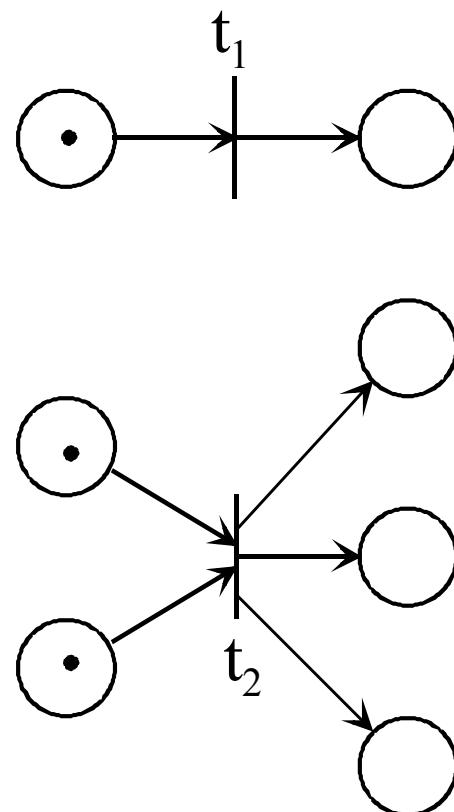

Assume that the money return operation is omitted.

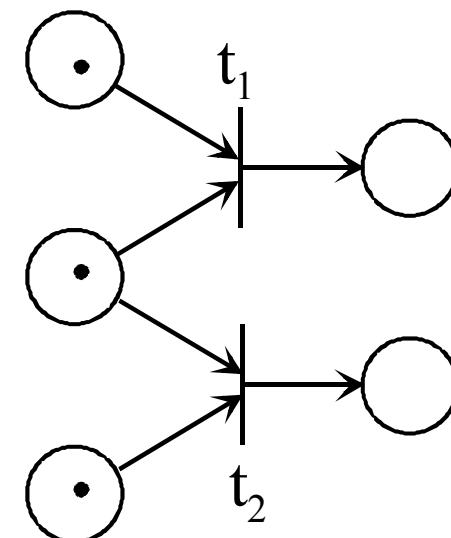

$p_1$ : machine with \$0.00;  
 $t_1, t_3, t_5, t_7$ : coin of 50 c introduced;  
 $t_2, t_4, t_6$ : coin of \$1 introduced;  
 $t_9$ : SODA A sold,  $t_8$ : SODA B sold.

## Petri nets: Modeling mechanisms

Concurrence

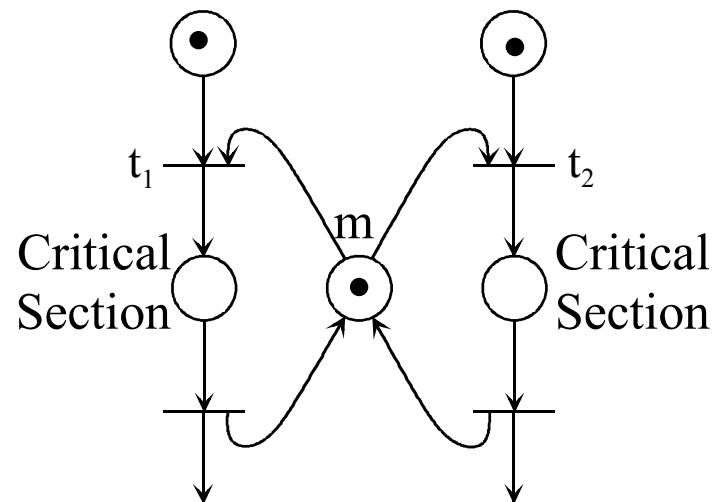

Conflict

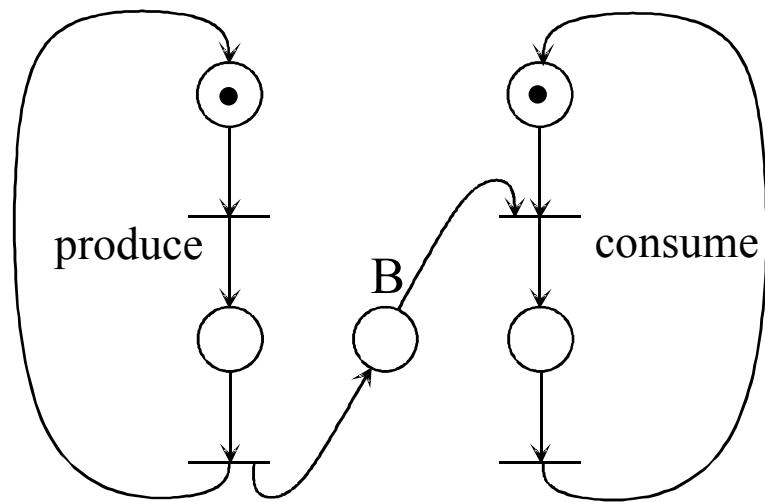

## Petri nets: Modeling mechanisms

Mutual Exclusion

Producer / Consumer

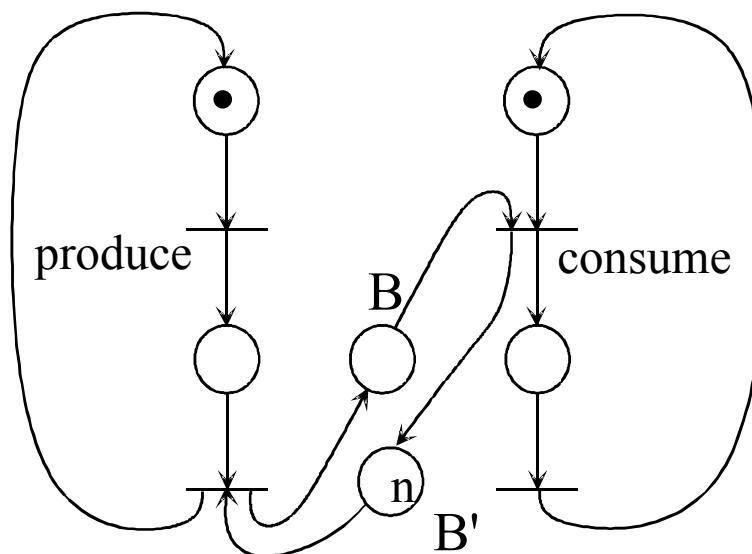

*Place  $m$  represents the permission to enter the critical section*

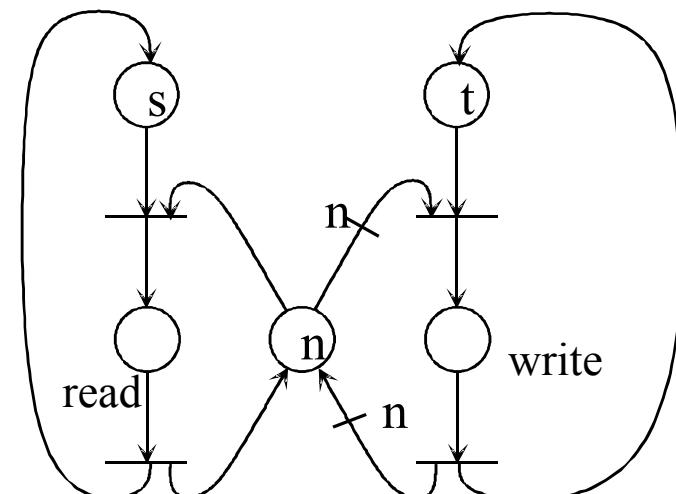

*$B$  = buffer holding produced parts*

## Petri nets: Modeling mechanisms

Producer / Consumer  
with finite capacity

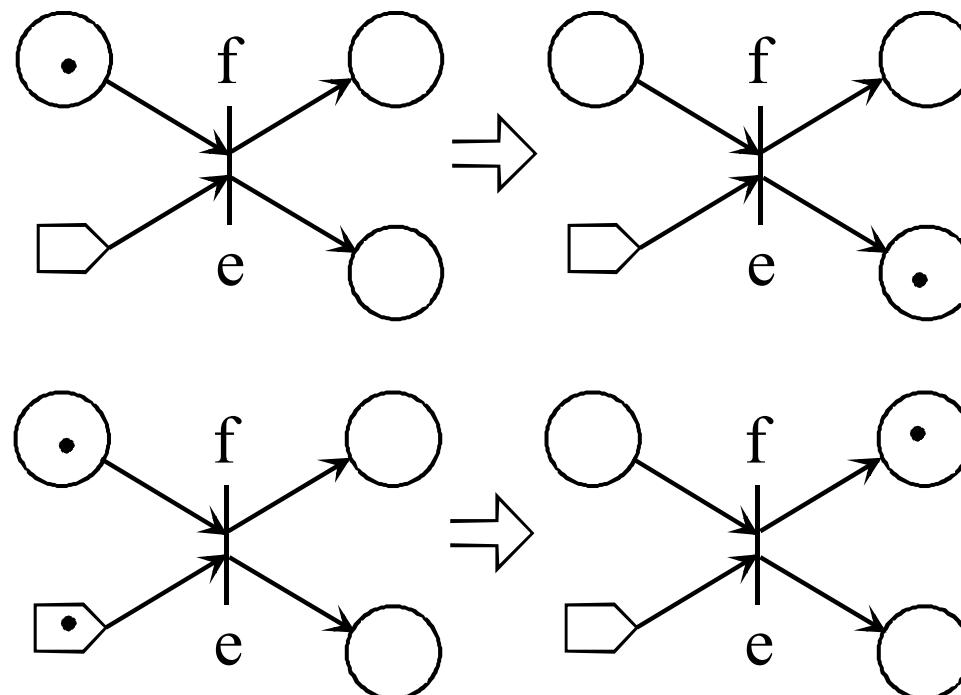

s Readers / t Writers

## Extensions to Petri nets

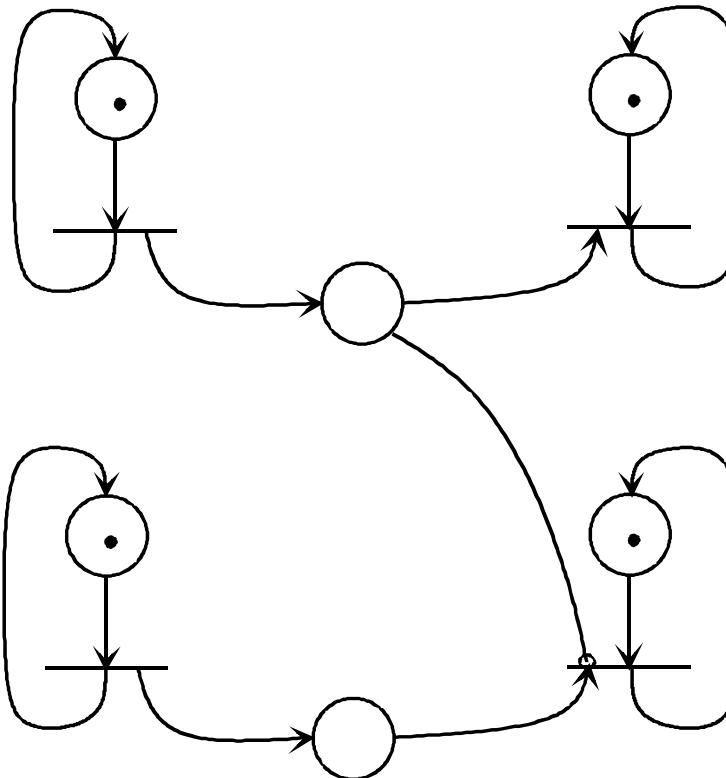

*Switches* [Baer 1973]

Possible to be implemented with restricted Petri nets.

## Extensions to Petri nets

**Inhibitor Arcs**  
**Equivalent to**  
**nets with priorities**

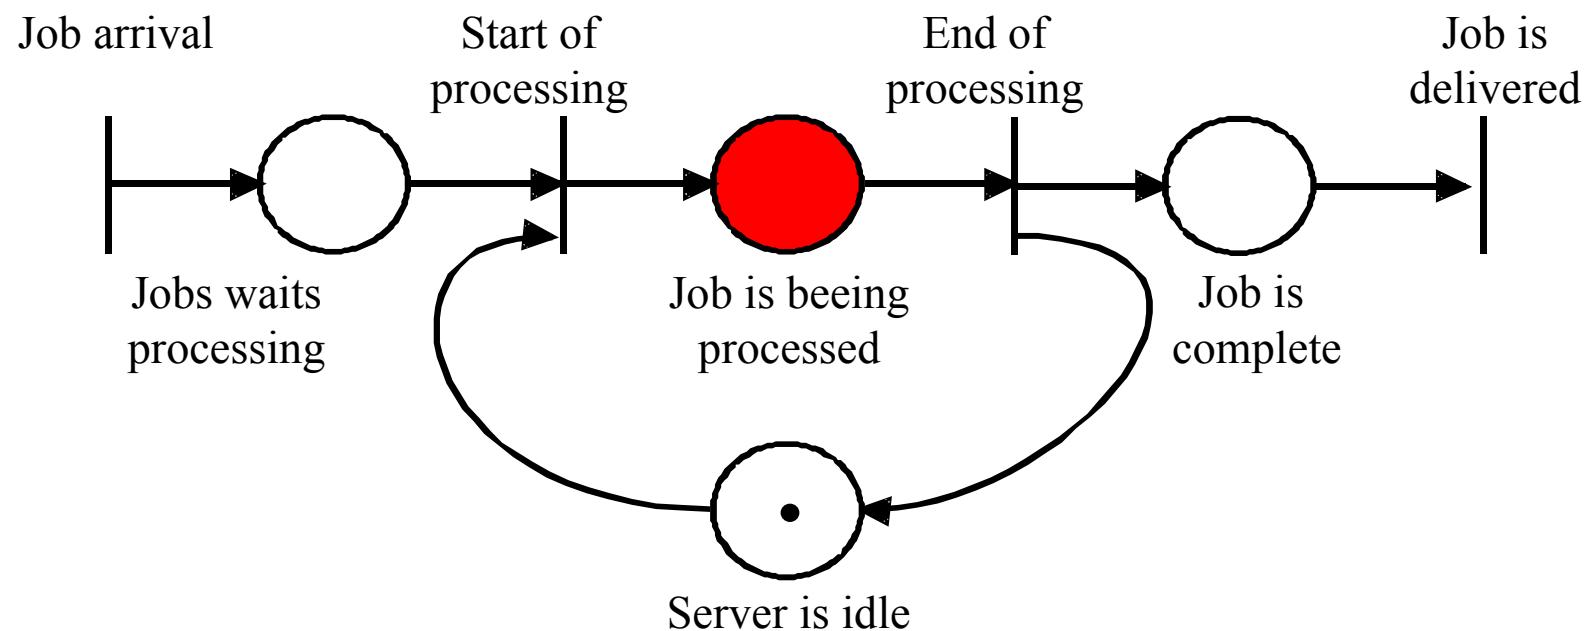

Can be implemented with restricted Petri nets?

Zero tests...

Infinity tests...

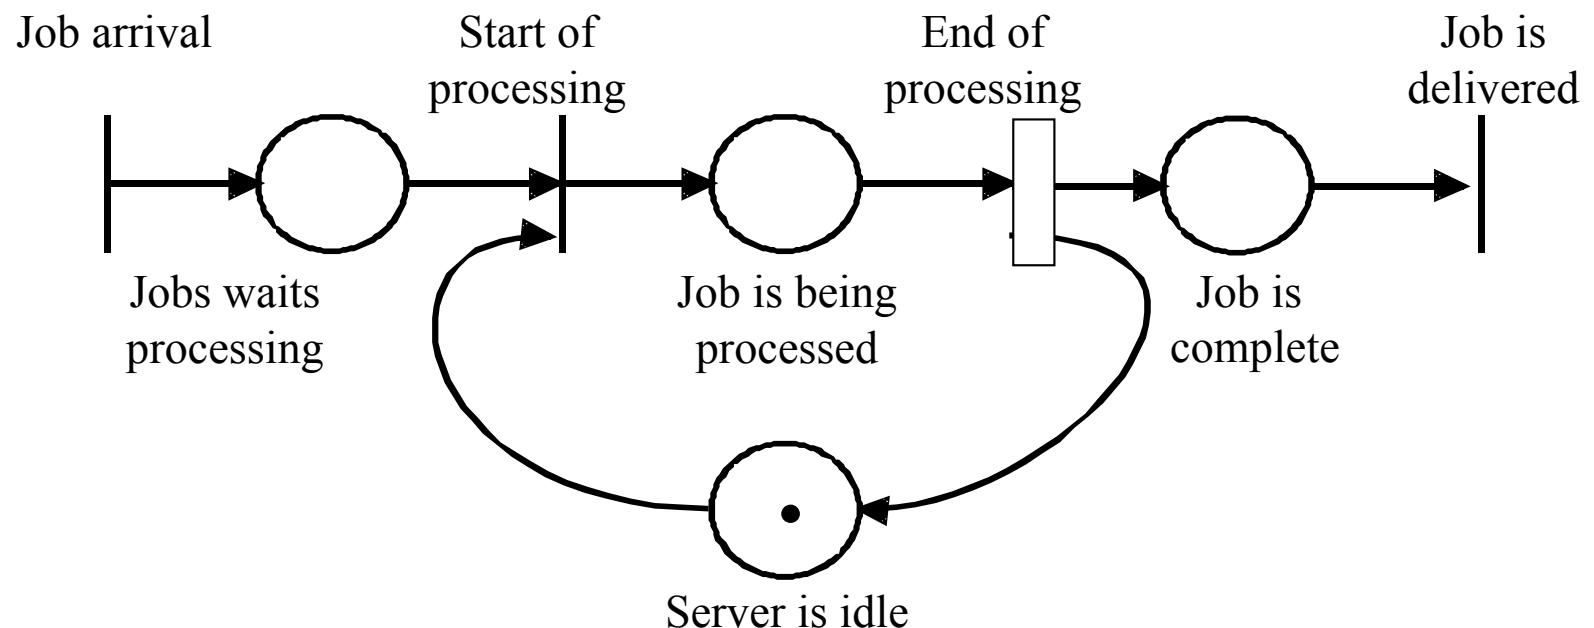

## Extensions to Petri nets

### P-Timed nets

## Extensions to Petri nets

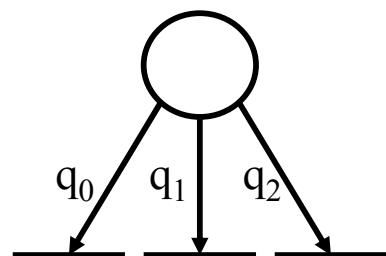

### T-Timed nets

## Extensions to Petri nets

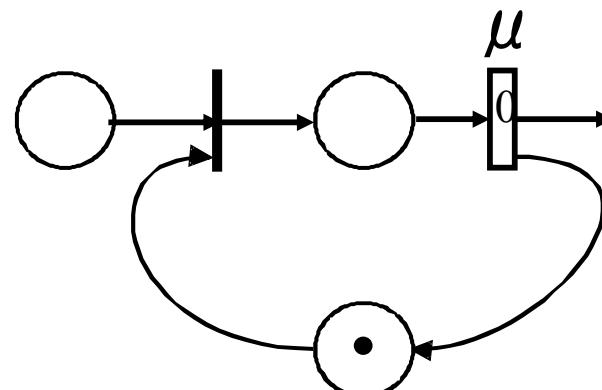

### Stochastic nets

Stochastic switches

$$q_0 + q_1 + q_2 = 1$$

Transitions with stochastic timings described by a stochastic variable with known pdf

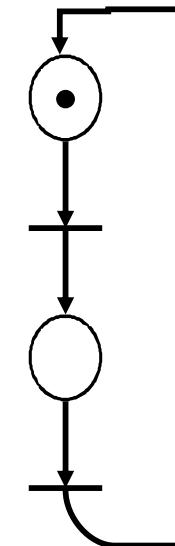

# Discrete Event Systems

## Sub-classes of Petri nets

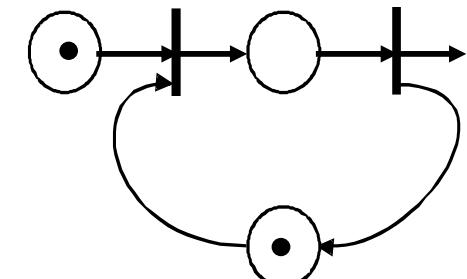

### State Machine:

Petri nets where each **transition** has exactly one **input arc** and **one output arc**.

### Marked Graphs:

Petri nets where each **place** has lesser than or equal to **one input arc** and **one output arc**.

# Discrete Event Systems

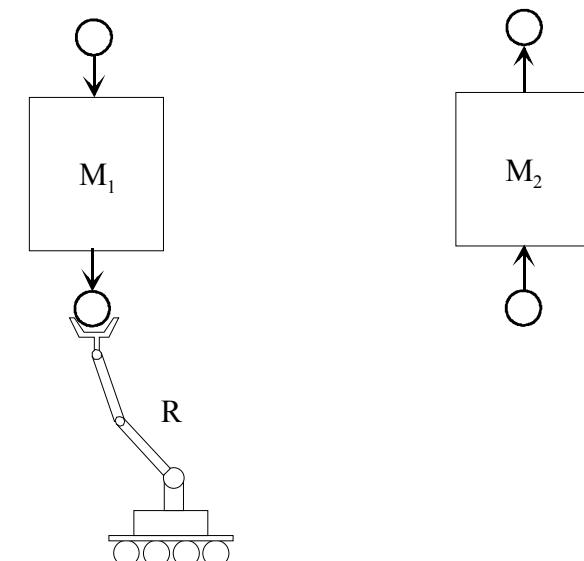

## Example of DES:

Manufacturing system composed by **2 machines** ( $M_1$  and  $M_2$ ) and a robotic **manipulator** (R). This takes the finished parts from machine  $M_1$  and transports them to  $M_2$ .

No buffers available on the machines.  
If R arrives near  $M_1$  and the machine is busy, the part is rejected.

If R arrives near  $M_2$  and the machine is busy, the manipulator must wait.

Machining time:  $M_1=0.5\text{s}$ ;  $M_2=1.5\text{s}$ ;  $R_{M1 \rightarrow M2}=0.2\text{s}$ ;  $R_{M2 \rightarrow M1}=0.1\text{s}$ ;

# Discrete Event Systems

## Example of DES:

Define places

- $M_1$       is characterized by places  $x_1$   
 $M_2$       is characterized by places  $x_2$   
 $R$         is characterized by places  $x_3$

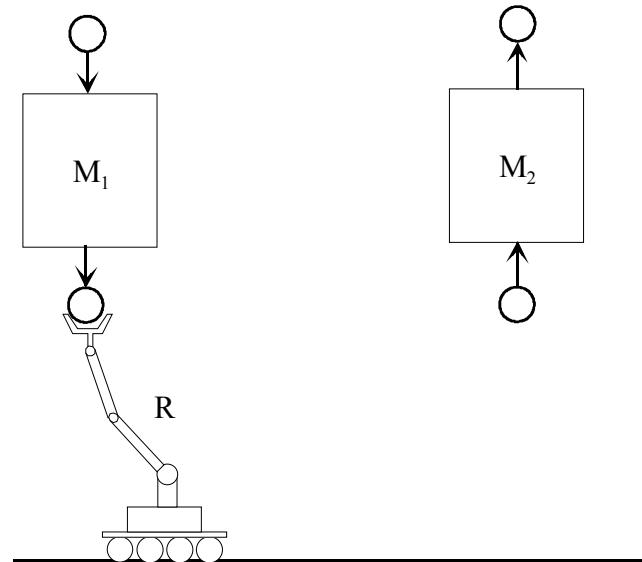

$x_1 = \{\text{Idle, Busy, Waiting}\}$

$x_2 = \{\text{Idle, Busy}\}$

$x_3 = \{\text{Idle, Carrying, Returning}\}$

Example of arrival of parts:

$$a(t) = \begin{cases} 1 & \text{in } \{0.1, 0.7, 1.1, 1.6, 2.5\} \\ 0 & \text{in other time stamps} \end{cases}$$

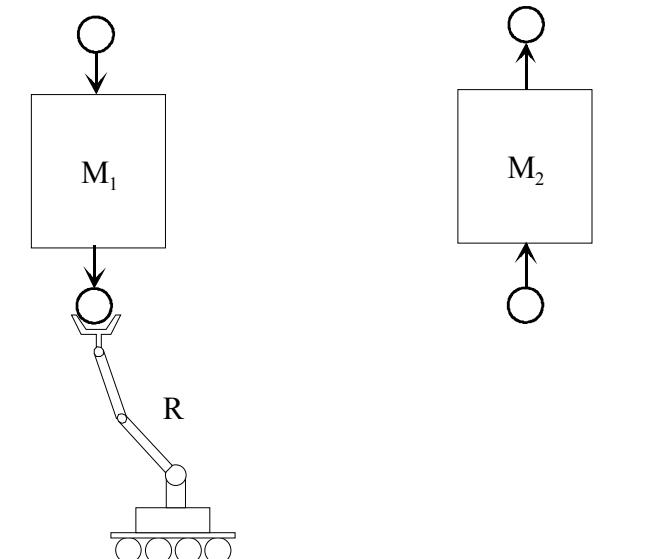

# Discrete Event Systems

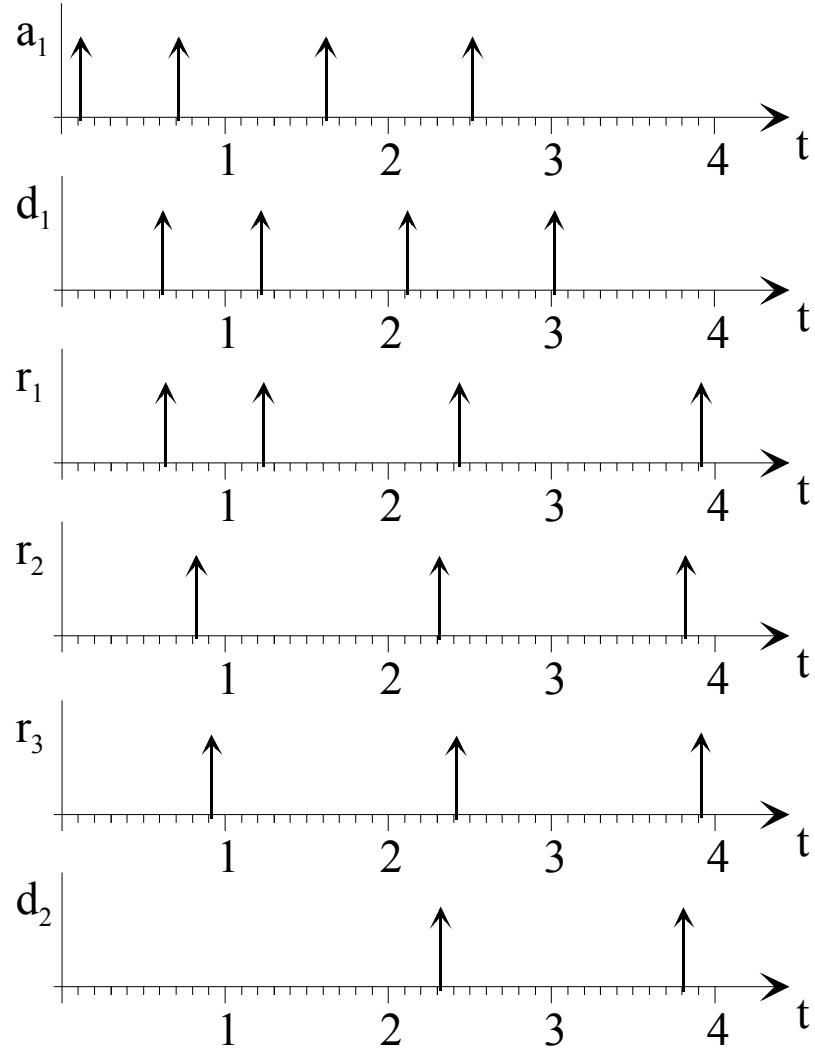

## Example of DES:

Definition of events:

- |       |  |
|-------|--|
| $a_1$ | - loads part in $M_1$                    |
| $d_1$ | - ends part processing in $M_1$          |
| <br>  |  |
| $r_1$ | - loads manipulator                      |
| $r_2$ | - unloads manipulator and<br>loads $M_2$ |
| <br>  |  |
| $d_2$ | - ends part processing in $M_2$          |
| $r_3$ | - manipulator at base                    |

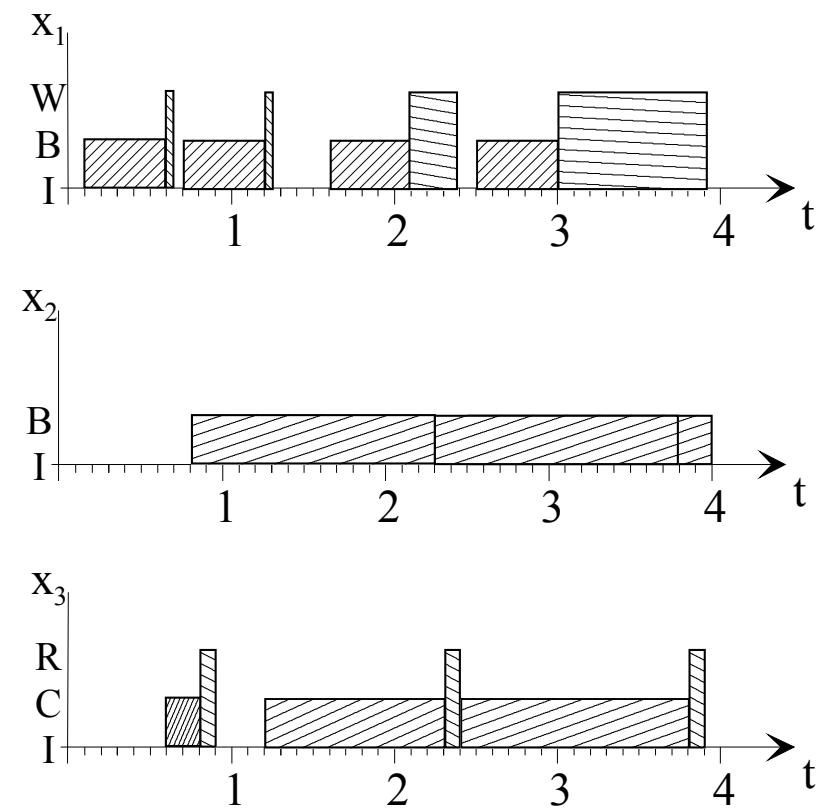

# Discrete Event Systems

$x_1 = \{\text{Idle}, \text{Busy}, \text{Waiting}\}$

$x_2 = \{\text{Idle}, \text{Busy}\}$

$x_3 = \{\text{Idle}, \text{Carrying}, \text{Returning}\}$

# Discrete Event Systems

## Example of DES:

Events:

- $a_1$  - loads part in  $M_1$
- $d_1$  - ends part processing in  $M_1$
- $r_1$  - loads manipulator
- $r_2$  - unloads manipulator and loads  $M_2$
- $d_2$  - ends part processing in  $M_2$
- $r_3$  - manipulator at base
