Prof. Paulo Jorge Oliveira, original slides Prof. José Gaspar, rev. 2016/2017

# Syllabus:

Chap. 5 – CAD/CAM and CNC [1 week]

• • •

Chap. 6 – Discrete Event Systems [2 weeks]

Discrete event systems modeling. Automata.

Petri Nets: state, dynamics, and modeling.

Extended and strict models. Subclasses of Petri nets.

• • •

Chap. 7 – Analysis of Discrete Event Systems [2 weeks]

#### Some pointers to Discrete Event Systems

History: <a href="http://prosys.changwon.ac.kr/docs/petrinet/1.htm">http://prosys.changwon.ac.kr/docs/petrinet/1.htm</a>

Tutorial: <a href="http://vita.bu.edu/cgc/MIDEDS/">http://vita.bu.edu/cgc/MIDEDS/</a>

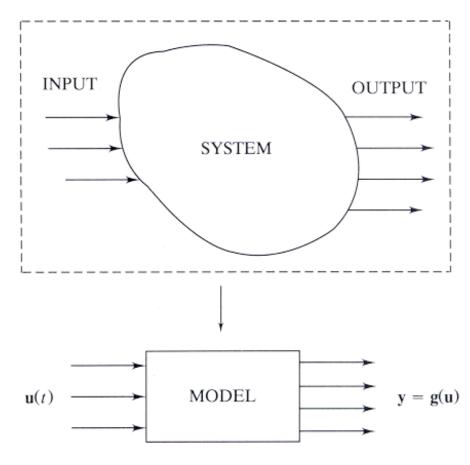

Figure 1.1. Simple modeling process.

Generic characterization of systems resorting to input / output relations

State equations:

$$\begin{cases} \dot{x}(t) = f(x(t), u(t), t) \\ y(t) = g(x(t), u(t), t) \end{cases}$$

in continuous time (or in discrete time)

Examples?

#### Control: Open loop vs closed-loop (⇔ the use of feedback)

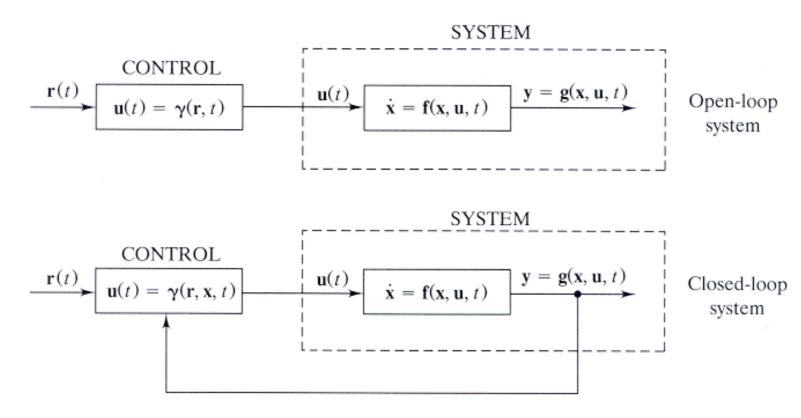

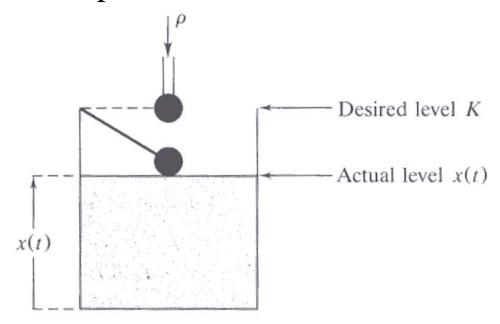

Figure 1.17. Open-loop and closed-loop systems.

#### Advantages of feedback?

(to revisit during DES supervision study)

#### Example of closed-loop with feedback

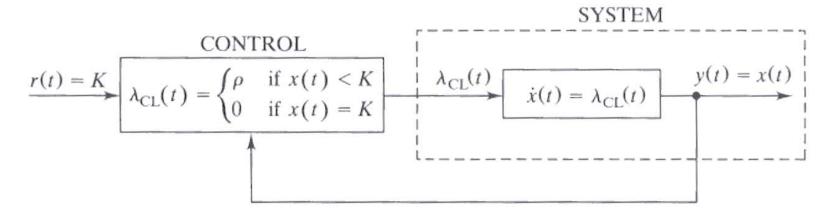

Figure 1.18. Flow system of Example 1.11 and closed-loop control model.

#### **Discrete Event Systems: Examples**

Set of events:

$$E=\{N, S, E, W\}$$

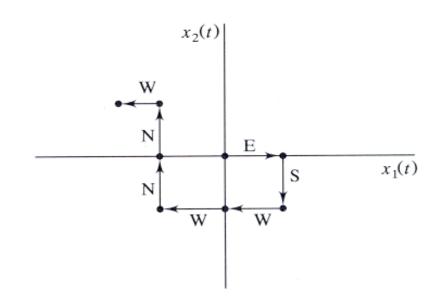

Figure 1.20. Random walk on a plane for Example 1.12.

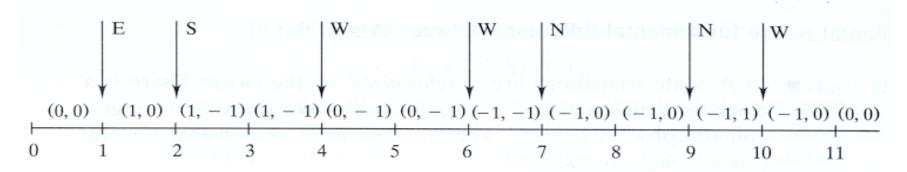

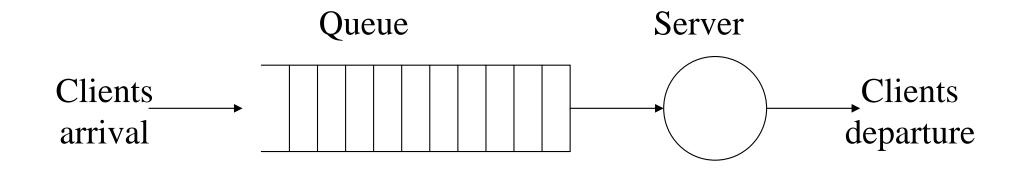

Figure 1.21. Event-driven random walk on a plane.

### **Discrete Event Systems: Examples**

Queueing systems

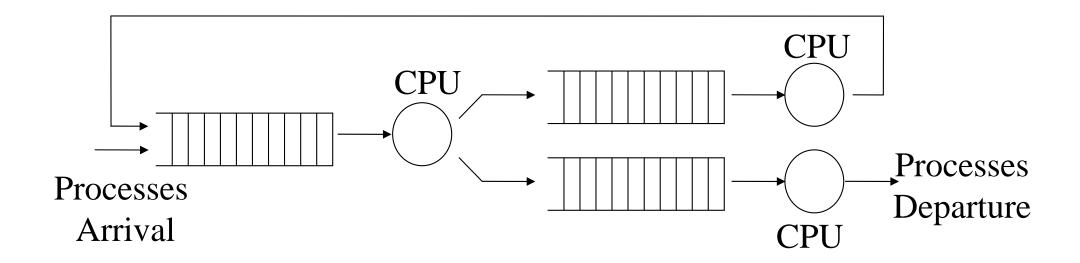

Set of events:

**E**= {arrival, departure}

## **Discrete Event Systems: Examples**

## **Computational Systems**

## Characteristics of systems with continuous variables

- 1. State space is continuous
- 2. The state transition mechanism is *time-driven*

#### Characteristics of systems with discrete events

- 1. State space is discrete
- 2. The state transition mechanism is event-driven

Intrinsic characteristic of discrete events systems: Polling is avoided!

# **Taxonomy of Systems**

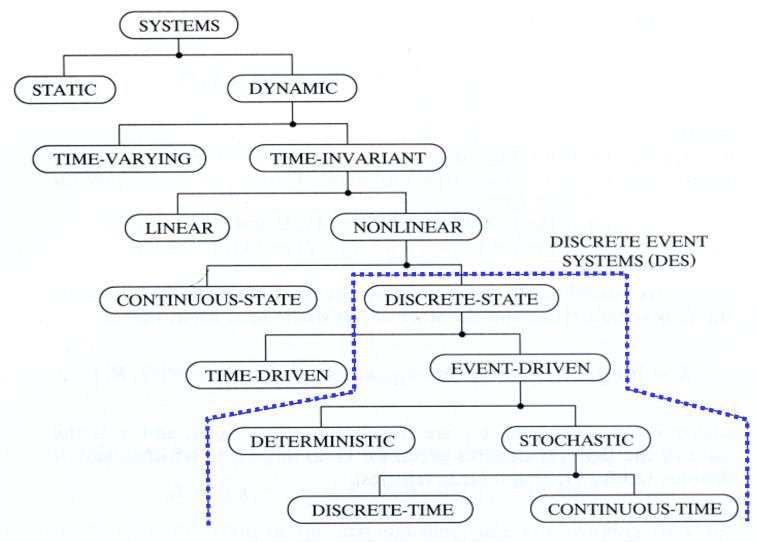

Figure 1.29. Major system classifications.

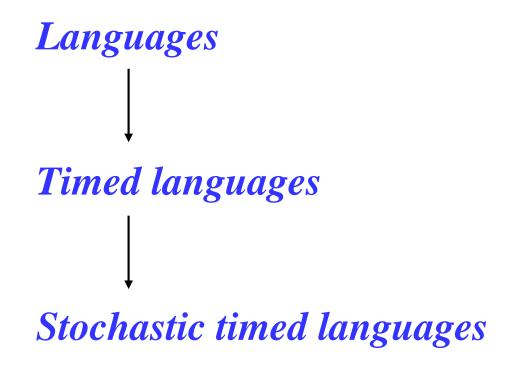

# Levels of abstraction in the study of Discrete Event Systems

Language of a "chocolate selling machine":

- (i) Waiting for a coin.
- (ii) Received 1 euro coin. Chocolate A given. Go to (i).
- (iii) Received 2 euro coin. Chocolate B given. Go to (i).

#### 4 sensors:

Received 1 euro coin, Received 2 euro coin, Chocolate A given, Chocolate B given.

# **Systems Theory Objectives**

- Modeling and Analysis
- *Design* and synthesis
- Control / Supervision
- Performance assessment and robustness
- Optimization

# **Applications of Discrete Event Systems**

- Queueing systems
- Operating systems and computers
- Telecommunications networks
- Distributed databases
- Automation

**Petri nets** 

Augmenting in

modeling capacity

&

complexity

#### **Automata Theory and Languages**

Genesis of computation theory

**Definition:** A **language** L, defined over the alphabet E is a set of *strings* of finite length with events from E.

Examples:  $\mathbf{E} = \{ \alpha, \beta, \gamma \}$   $L_1 = \{ \epsilon, \alpha \alpha, \alpha \beta, \gamma \beta \alpha \}, \text{ where } \epsilon \text{ is the null/empty string}$   $L_2 = \{ \text{all } \textit{strings} \text{ of length } 3 \}$ 

How to build a machine that "talks" a given language?

or

What language "talks" a system?

#### Operations / Properties of languages

 $E^* =$ Kleene-closure of E: set of all strings of finite length of E, including the null element  $\mathcal{E}$ .

**Concatenation** of  $L_a$  and  $L_b$ :

$$L_a L_b := \{ s \in E^* : s = s_a s_b, s_a \in L_a, s_b \in L_b \}$$

**Prefix-closure** of  $L \subseteq E^*$ :

$$\overline{L} := \left\{ s \in E^* : \exists_{t \in E^*} \ st \in L \right\}$$

### Operations / Properties of languages

#### Example 2.1 (Operations on languages)

Let  $E = \{a, b, g\}$ , and consider the two languages  $L_1 = \{\varepsilon, a, abb\}$  and  $L_4 = \{g\}$ . Neither  $L_1$  nor  $L_4$  are prefix-closed, since  $ab \notin L_1$  and  $\varepsilon \notin L_4$ . Then:

```
L_{1}L_{4} = \{g, ag, abbg\}
\overline{L_{1}} = \{\varepsilon, a, ab, abb\}
\overline{L_{4}} = \{\varepsilon, g\}
L_{1}\overline{L_{4}} = \{\varepsilon, a, abb, g, ag, abbg\}
L_{4}^{*} = \{\varepsilon, g, gg, ggg, \ldots\}
L_{1}^{*} = \{\varepsilon, a, abb, aa, aabb, abba, abbabb, \ldots\}
```

[Cassandras99]

#### **Automata Theory and Languages**

Motivation: An automaton is a device capable of representing a language according to some rules.

**Definition:** A deterministic **automaton** is a 5-tuple

$$(\mathbf{E}, \mathbf{X}, \mathbf{f}, \mathbf{x}_0, \mathbf{F})$$

where:

**E** - finite alphabet (or possible events)

**X** - finite set of states

**f** - state transition function  $\mathbf{f}: \mathbf{X} \times \mathbf{E} \rightarrow \mathbf{X}$ 

 $\mathbf{x_0}$  - initial state  $\mathbf{x_0} \subset \mathbf{X}$ 

 $\mathbf{F}$  - set of final states or marked states  $\mathbf{F} \subset \mathbf{E}$ 

[Cassandras93]

Word of caution: the word "state" is used here to mean "step" (Grafcet) or "place" (Petri Nets)

#### Example 1 of an automaton:

$$(E, X, f, x_0, F)$$

$$\mathbf{E} = \{ \alpha, \beta, \gamma \}$$

$$\mathbf{X} = \{x, y, z\}$$

$$\mathbf{x_0} = \mathbf{x}$$

$$\mathbf{F} = \{\mathbf{x}, \mathbf{z}\}$$

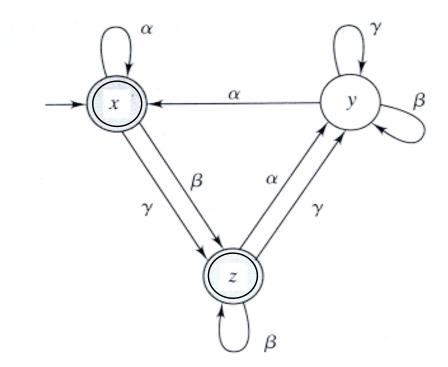

Figure 2.1. State transition diagram for Example 2.3.

$$f(x, \alpha) = x$$
  $f(x, \beta) = z$   $f(x, \gamma) = z$   
 $f(y, \alpha) = x$   $f(y, \beta) = y$   $f(y, \gamma) = y$   
 $f(z, \alpha) = y$   $f(z, \beta) = z$   $f(z, \gamma) = y$ 

#### Example 2 of a stochastic automaton

$$(E, X, f, x_0, F)$$

$$\mathbf{E} = \{ \alpha, \beta \}$$

$$X = \{0, 1\}$$

$$\mathbf{x_0} = 0$$

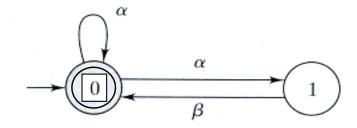

Figure 2.4. State transition diagram for the nondeterministic automaton of Example 2.7.

$$f(0, \alpha) = \{0, 1\}$$
  $f(0, \beta) = \{\}$   
 $f(1, \alpha) = \{\}$   $f(1, \beta) = 0$ 

Given an automaton

$$G = (E, X, f, x_0, F)$$

the Generated Language is defined as

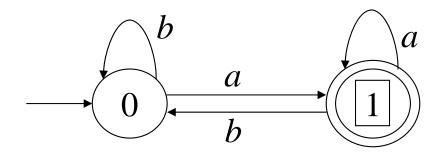

$$L(G) := \{s \in E^* : f(x_0,s) \text{ is defined}\}$$

*Note: if f is always defined then*  $L(G)==E^*$ 

and the Marked Language is defined as

$$L_m(G) := \{ s \in E^* : f(x_0, s) \in F \}$$

#### Example 3: marked language of an automaton

$$L(G) := \{ \mathcal{E}, a, b, aa, ab, ba, bb, aaa, aab, baa, ... \}$$

$$L_m(G) := \{a, aa, ba, aaa, baa, bba, \ldots\}$$

Concluding, in this example  $L_m(G)$  means all strings with events a and b, ended by event a.

### Automata equivalence:

The automata  $G_1$  e  $G_2$  are equivalent if

$$L(G_1) = L(G_2)$$
and
$$I(G_1) - I(G_2)$$

#### Example 4: two equivalent automata

Objective: To validate a sequence of events

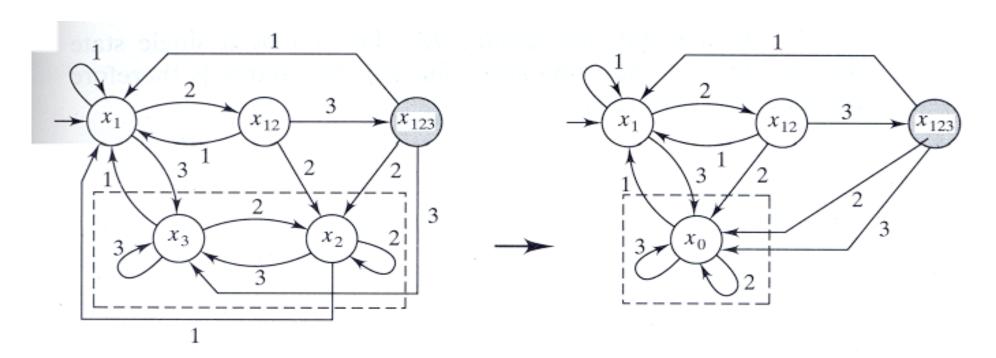

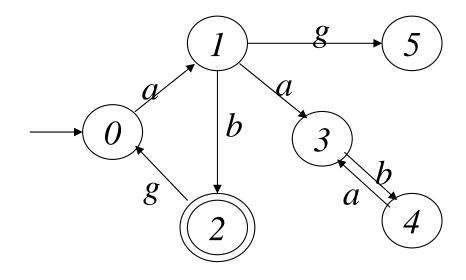

Figure 2.6. State transition diagrams for digit sequence detector in Example 2.9.

Deadlocks (inter-blocagem)

#### Example 5:

The state 5 is a deadlock.

The states 3 and 4 constitute a *livelock*.

How to find the *deadlocks* and the *livelocks*?

Need methodologies for the analysis of Discrete Event Systems

#### Deadlock:

in general the following relations are verified

$$L_m(G)\subseteq \overline{L}_m(G)\subseteq L(G)$$

An automaton G has a deadlock if

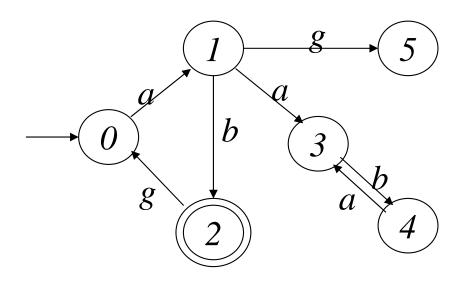

$$\overline{L}_m(G) \subset L(G)$$

and is not blocked when

$$\overline{L}_m(G) = L(G)$$

Deadlock:

Example:

The state 5 is a deadlock.

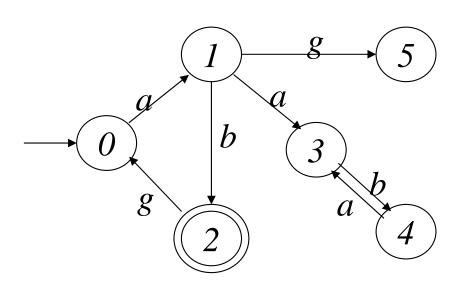

The states 3 and 4 constitute a *livelock*.

$$L_{m}(G) = \{ab, abgab, abgabgab, ...\}$$
 $L(G) = \{\varepsilon, a, ab, ag, aa, aab, \\ abg, aaba, abga, ...\}$ 
 $(L_{m}(G) \subset L(G))$ 

$$\overline{L}_m(G) \neq L(G)$$

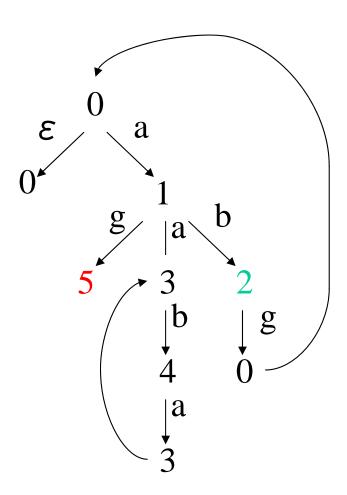

#### Alternative way to detect deadlocks:

## Example:

The state 5 is a deadlock.

The states 3 and 4 constitute a *livelock*.

#### **Timed Discrete Event Systems**

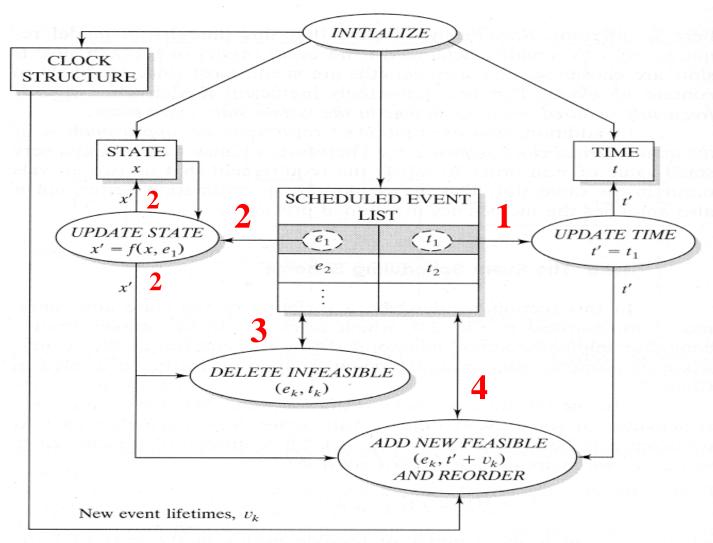

Figure 3.10. The event scheduling scheme.

#### **Examples of Automata Classes and Applications**

Automaton Class	Recognizable language	Applications
Finite state machine (FSM), e.g. Moore machines or Mealy machines	Regular languages	Text processing, compilers, and hardware design
Pushdown automaton (PDA)	Context-free languages	Programming languages, artificial intelligence, (originally) study of the human languages
Turing machine (nondeterministic, deterministic, multitape,)	Recursively enumerable languages	Theory, complexity

#### **Petri nets**

Developed by Carl Adam Petri in his PhD thesis in 1962.

**Definition:** A marked Petri net is a *5-tuple* 

$$(\mathbf{P}, \mathbf{T}, \mathbf{A}, \mathbf{w}, \mathbf{x}_0)$$

where:

**P** - set of places

T - set of transitions

A - set of arcs  $A \subseteq (P \times T) \cup (T \times P)$ 

 $\mathbf{w}$  - weight function  $\mathbf{w} : \mathbf{A} \to \mathbf{N}$ 

 $\mathbf{x}_0$  - initial marking  $\mathbf{x}_0:\mathbf{P}\to\mathbf{N}$ 

[Cassandras93]

#### Example of a Petri net

$$(P, T, A, w, x_0)$$

$$P=\{p_1, p_2, p_3, p_4, p_5\}$$

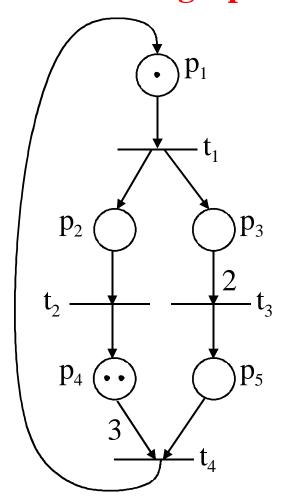

$$T = \{t_1, t_2, t_3, t_4\}$$

A={
$$(p_1, t_1), (t_1, p_2), (t_1, p_3), (p_2, t_2), (p_3, t_3), (t_2, p_4), (t_3, p_5), (p_4, t_4), (p_5, t_4), (t_4, p_1)}$$

$$w(p_1, t_1)=1, w(t_1, p_2)=1, w(t_1, p_3)=1, w(p_2, t_2)=1$$
  
 $w(p_3, t_3)=2, w(t_2, p_4)=1, w(t_3, p_5)=1, w(p_4, t_4)=3$   
 $w(p_5, t_4)=1, w(t_4, p_1)=1$ 

$$\mathbf{x}_0 = \{1, 0, 0, 2, 0\}$$

#### Petri net graph

#### **Petri nets**

Rules to follow (mandatory):

- Arcs (directed connections)

  connect places to transitions and
  connect transitions to places
- A transition can have no places directly as inputs (source), i.e. must exist arcs between transitions and places
- A transition can have no places directly as outputs (sink), i.e. must exist arcs between transitions and places
- The same happens with the input and output transitions for places

#### Alternative definition of a Petri net

A marked Petri net is a 5-tuple

 $(\mathbf{P}, \mathbf{T}, \mathbf{I}, \mathbf{O}, \mu_0)$ 

where:

**P** - set of places

**T** - set of transitions

I - transition input function I:  $T \to P^{\infty}$ 

O - transition output function  $O: T \to P^{\infty}$ 

 $\mu_0$  - initial marking  $\mu_0: P \to N$ 

[Peterson81]

Note:  $P^{\infty}$  = bag of places (is more general than a set of places)

#### Example of a Petri net and its graphical representation

Alternative definition

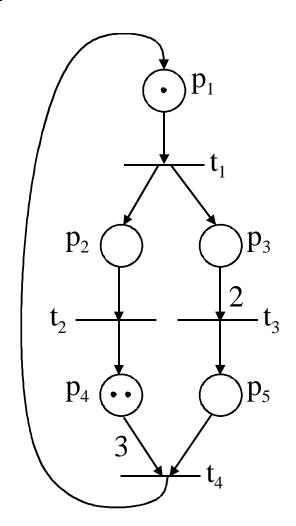

$$(P, T, I, O, \mu_0)$$

$$P=\{p_1, p_2, p_3, p_4, p_5\}$$

$$T = \{t_1, t_2, t_3, t_4\}$$

$$\begin{split} &I(t_1) = \{p_1\} & O(t_1) = \{p_2, p_3\} \\ &I(t_2) = \{p_2\} & O(t_2) = \{p_4\} \\ &I(t_3) = \{p_3, p_3\} & O(t_3) = \{p_5\} \\ &I(t_4) = \{p_4, p_4, p_4, p_5\} & O(t_4) = \{p_1\} \end{split}$$

$$\mu_0 = \{1, 0, 0, 2, 0\}$$

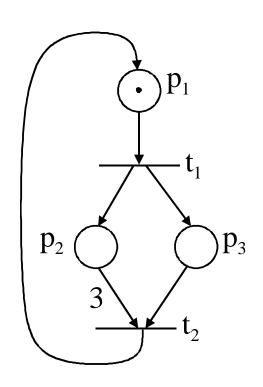

### Petri nets: State, Markings, Weights of Arcs

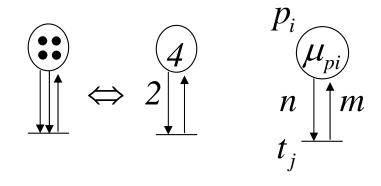

The state of a Petri net is characterized by the marking of all places.

The set of all possible markings of a Petri net corresponds to its state space.

How does the state of a Petri net evolve?

Nomenclature for the markings and cardinality (weight) of the arcs:

$$n = \#(p_i, I(t_j))$$

$$m = \#(p_i, O(t_j))$$

## Execution Rules for Petri Nets (Dynamics of Petri nets)

A transition  $t_i \in T$  is *enabled* if:

$$\forall p_i \in P: \quad \mu(p_i) \geq \#(p_i, I(t_j))$$

A transition  $t_j \in T$  may *fire* whenever enabled, resulting in a new marking given by:

$$\mu'(p_i) = \mu(p_i) - \#(p_i, I(t_j)) + \#(p_i, O(t_j))$$

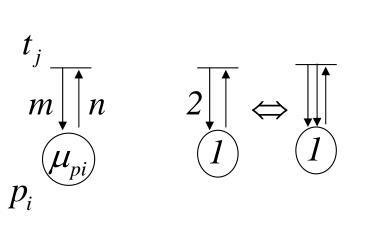

$$\#(p_i, I(t_j)) = multiplicity of the arc from p_i to t_j$$
  
 $\#(p_i, O(t_j)) = multiplicity of the arc from t_j to p_i$ 

[Peterson81 **§** 2.3]

#### **Execution Rules for Petri Nets**

(Dynamics of Petri nets)

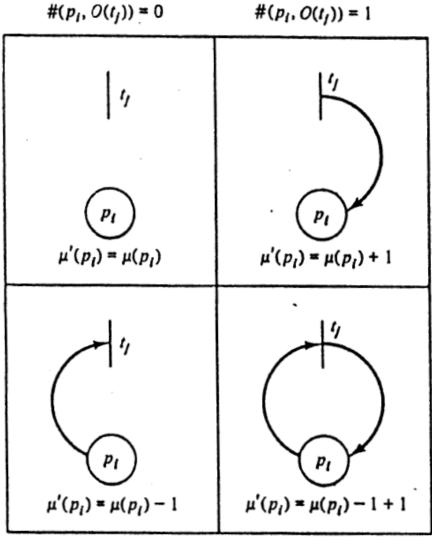

$$\#(p_i,\,I(t_j))=0$$

$$n = \#(p_i, I(t_j))$$

$$m = \#(p_i, O(t_j))$$

$$\#(p_i, I(t_j)) = 0$$
 $\#(p_i, I(t_j)) = 1$ 

$$\mu'(p_i) = \mu(p_i) - \#(p_i, I(t_j)) + \#(p_i, O(t_j))$$

[Peterson81 **§**2.3]

#### **Petri nets**

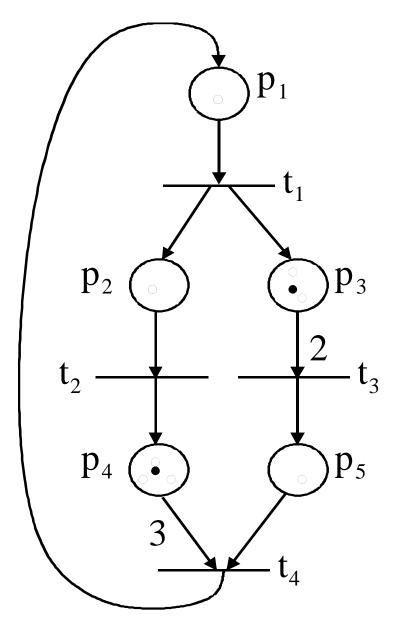

Example of evolution of a Petri net

Initial marking:

$$\mu_0 = \{1, 0, 1, 2, 0\}$$

This discrete event system can not change state.

It is in a deadlock!

#### **Petri nets: Conditions and Events (Places and Transitions)**

Example: Machine waits until an order appears and then machines the ordered part and sends it out for delivery.

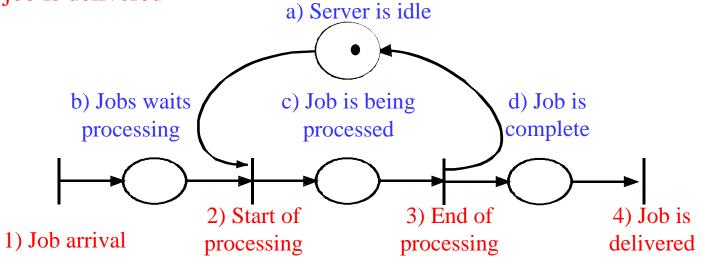

#### **Conditions:**

- a) The server is idle.
- b) A job arrives and waits to be processed
- c) The server is processing the job
- d) The job is complete

#### **Events**

- Job arrival
- 2) Server starts processing
- 3) Server finishes processing
- 4) The job is delivered

Event	Pre-	Pos-
	conditions	conditions
1	-	b
2	a, b	С
3	С	d, a
4	d	_

## Example of a simple automation system modeled using PNs

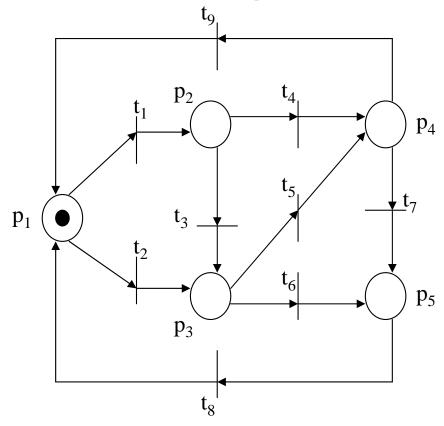

An automatic soda selling machine accepts

50c and \$1 coins and

sells 2 types of products:

SODA A, that costs \$1.50 and SODA B, that costs \$2.00.

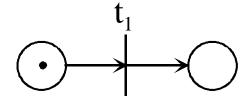

Assume that the money return operation is omitted.

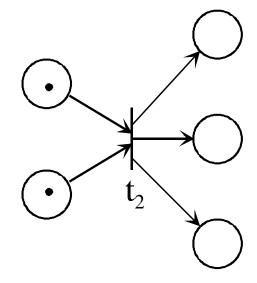

p<sub>1</sub>: machine with \$0.00; t<sub>1</sub>,t<sub>3</sub>,t<sub>5</sub>,t<sub>7</sub>: coin of 50 c introduced; t<sub>2</sub>,t<sub>4</sub>,t<sub>6</sub>: coin of \$1 introduced; t<sub>9</sub>: SODA A sold, t<sub>8</sub>: SODA B sold.

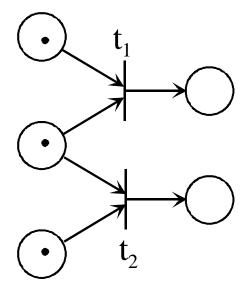

# Petri nets: Modeling mechanisms

Concurrence

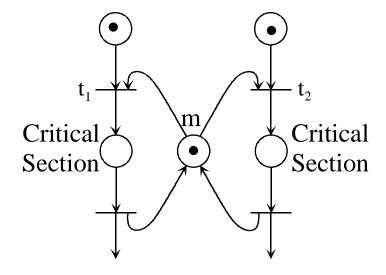

#### Conflict

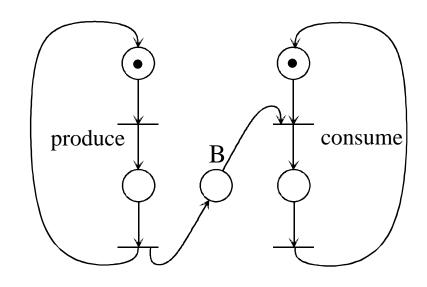

## Petri nets: Modeling mechanisms

#### **Mutual Exclusion**

Place m represents the permission to enter the critical section

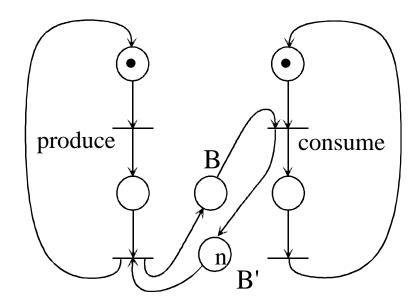

#### Producer / Consumer

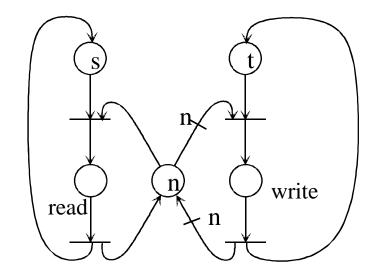

*B*= *buffer holding produced parts* 

## **Petri nets: Modeling mechanisms**

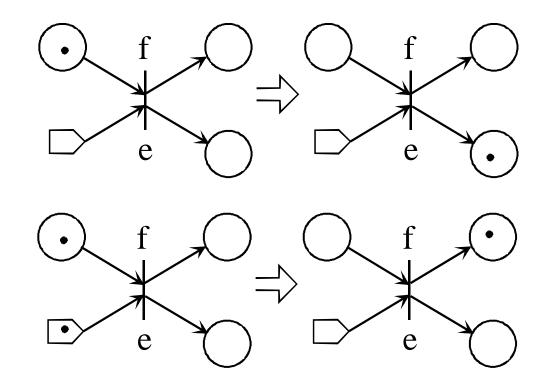

Producer / Consumer with finite capacity

s Readers / t Writers

#### Switches [Baer 1973]

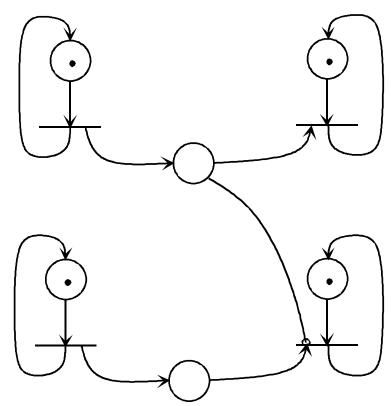

Possible to be implemented with restricted Petri nets.

**Inhibitor Arcs** 

**Equivalent to** 

nets with priorities

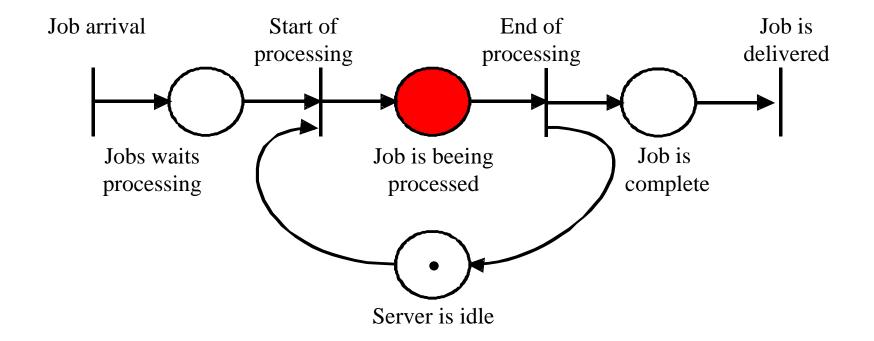

Can be implemented with restricted Petri nets?

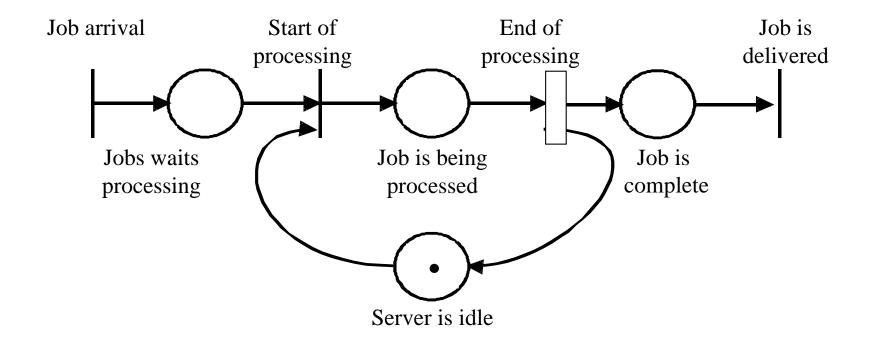

Zero tests...

Infinity tests...

#### **P-Timed nets**

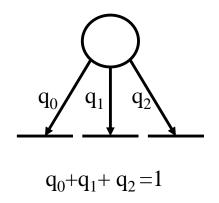

#### **T-Timed nets**

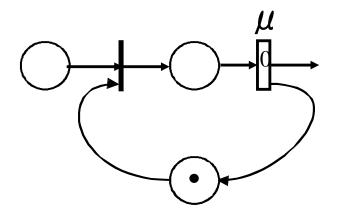

#### **Stochastic nets**

#### Stochastic switches

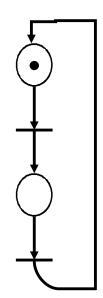

Transitions with stochastic timings described by a stochastic variable with known pdf

# **Discrete Event Systems Sub-classes of Petri nets**

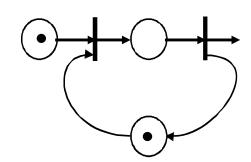

#### **State Machine:**

Petri nets where each transition has exactly one input arc and one output arc.

#### **Marked Graphs:**

Petri nets where each place has lesser than or equal to one input arc and one output arc.

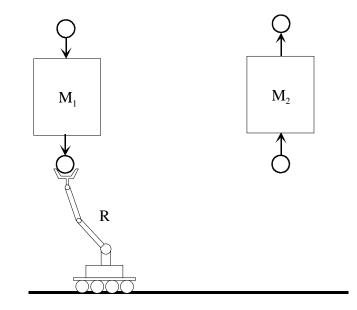

## **Example of DES:**

Manufacturing system composed by **2 machines** ( $M_1$  and  $M_2$ ) and a robotic **manipulator** (R). This takes the finished parts from machine  $M_1$ and transports them to  $M_2$ .

No buffers available on the machines. If R arrives near  $M_1$  and the machine is busy, the part is rejected.

If R arrives near  $M_2$  and the machine is busy, the manipulator must wait.

Machining time:  $M_1=0.5s$ ;  $M_2=1.5s$ ;  $R_{M1 \to M2}=0.2s$ ;  $R_{M2 \to M1}=0.1s$ ;

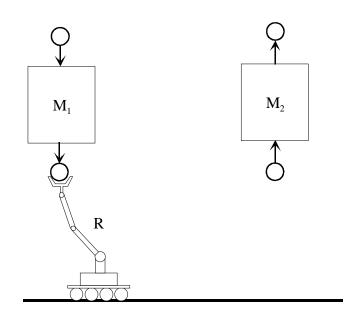

#### **Example of DES:**

#### Define places

M<sub>1</sub> is characterized by places x<sub>1</sub>
 M<sub>2</sub> is characterized by places x<sub>2</sub>
 R is characterized by places x<sub>3</sub>

Example of arrival of parts:

$$a(t) = \begin{cases} 1 & in & \{0.1, 0.7, 1.1, 1.6, 2.5\} \\ 0 & in & other time stamps \end{cases}$$

## **Example of DES:**

#### Definition of events:

a<sub>1</sub> - loads part in M<sub>1</sub>

d<sub>1</sub> - ends part processing in M<sub>1</sub>

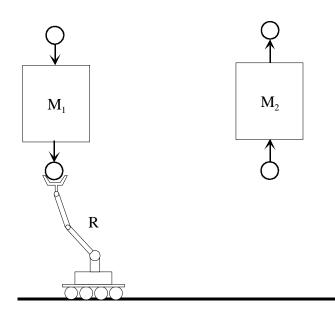

r<sub>1</sub> - loads manipulator

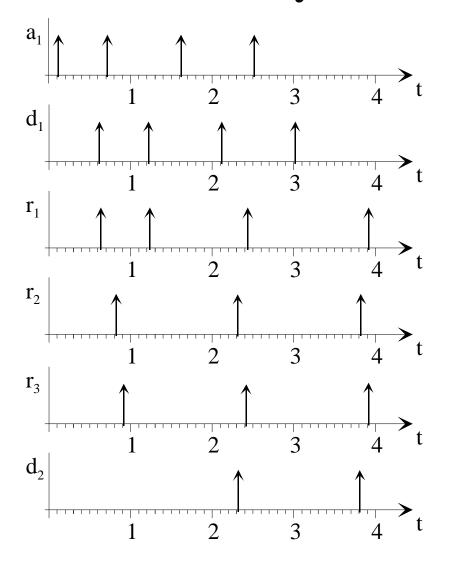

r<sub>2</sub> - unloads manipulator and

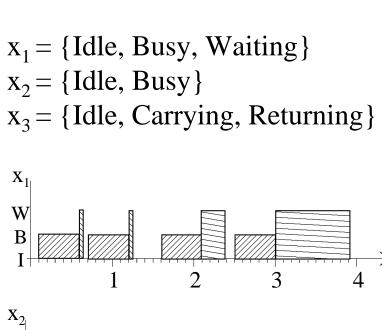

loads M<sub>2</sub>

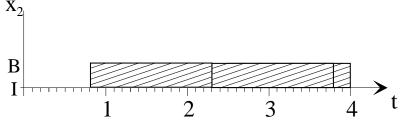

d<sub>2</sub> - ends part processing in M<sub>2</sub>

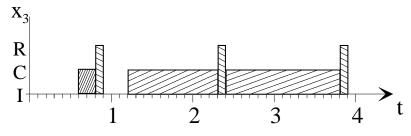

r<sub>3</sub> - manipulator at base

# **Discrete Event Systems Example of DES:**

#### **Events:**

 $a_1$  - loads part in  $M_1$ 

 $d_1$  - ends part processing in  $M_1$ 

r<sub>1</sub>- loads manipulator

r<sub>2</sub>- unloads manipulator and loads M<sub>2</sub>

d<sub>2</sub>- ends part processing in M<sub>2</sub>

r<sub>3</sub>- manipulator at base
