Generic characterization of systems resorting to input / output relations

Case1: each input determines a single output value

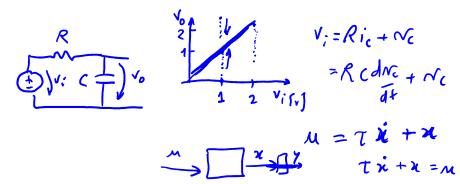

Case2: **dynamic system**, an input implies a time evolving response.

Typically, one uses state space equations:

 $\begin{cases} \dot{x}(t) = f(x(t), u(t), t) \\ y(t) = g(x(t), u(t), t) \end{cases}$

in continuous time (or in discrete time).

Example / Comment: voltage divider circuit vs RC circuit (capacitor charge circuit), given an input one cannot tell the capacitor voltage without knowing its initial condition.

Control: Open loop vs closed-loop (⇔ the use of feedback)

Discrete Event Systems: Examples

Consider e.g. a milk distribution truck in Manhattan. How to model its motion?

Set of events $\mathbf{E} = \{N, S, E, W\}$

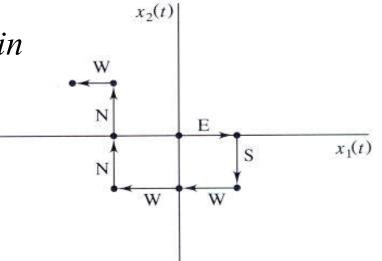

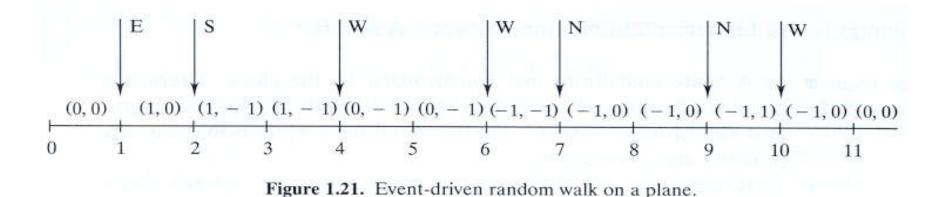

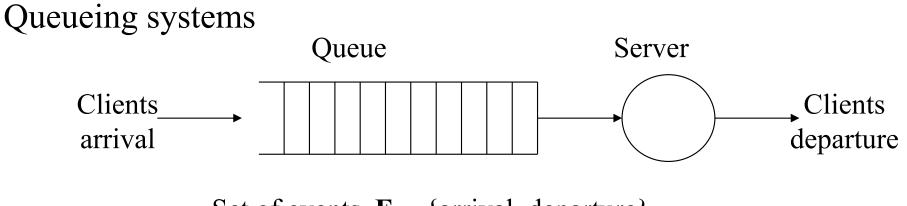

Figure 1.20. Random walk on a plane for Example 1.12.

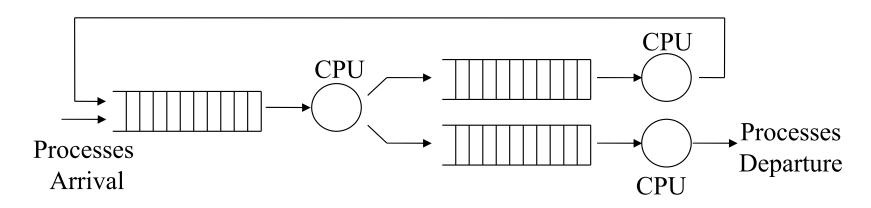

Discrete Event Systems: Examples

Set of events, **E** = {arrival, departure}

Computational Systems

Characteristics of systems with continuous variables

- 1. State space is continuous
- 2. The state transition mechanism is *time-driven*

Characteristics of systems with discrete events (DES)

- 1. State space is discrete
- 2. The state transition mechanism is *event-driven*

Intrinsic characteristic of discrete events systems: Polling is avoided!

Taxonomy of Systems

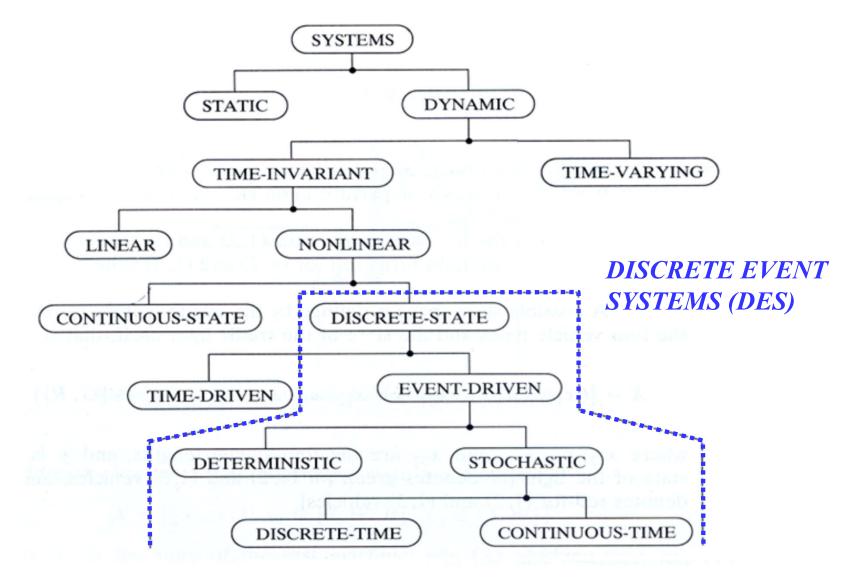

Figure 1.29: Major system classification

Levels of abstraction in the study of Discrete Event Systems

Example 1: Language of a "chocolate selling machine":

(i) Waiting for a coin.
(ii) Received 1 euro coin. Chocolate A given. Go to (i).
(iii) Received 2 euro coin. Chocolate B given. Go to (i).

2 actuators: *Give chocolate A Give chocolate B*

4 sensors:

Received 1 euro coin, Received 2 euro coin, Chocolate A given, Chocolate B given. Q: How to model (i) a self playing piano / "pianola", (ii) a recognizer of digits spoken by a person?

Stochastic timed languages

Languages

Timed languages

Systems Theory Objectives

- Modeling and Analysis
- *Design* and synthesis
- Control / Supervision
- Performance assessment and robustness
- Optimization

Applications of Discrete Event Systems

- Queueing systems
- Operating systems and computers
- Telecommunications networks
- Distributed databases
- Automation

Discrete Event Systems

Typical modeling methodologies

Automata

GRAFCET/SFC

Augmenting in

modeling capacity &

complexity

Petri nets

Automata Theory and Languages - Genesis of computation theory

Definition: A **language** L, defined over the alphabet E is a **set of** *strings* of finite length with events from E.

Examples:

 $\mathbf{E}=\{\alpha,\,\beta,\,\gamma\}$

 $L_1 = \{\epsilon, \alpha \alpha, \alpha \beta, \gamma \beta \alpha\}$, where ϵ is the null/empty string $L_2 = \{all strings of length 3\}$

How to build a machine that "talks" a given language?

Oľ

What language "talks" a system?

Operations / Properties of languages

 $E^* =$ Kleene-closure of *E*: set of all strings of finite length of E, including the null element ε .

Concatenation of L_a and L_b :

$$L_a L_b \coloneqq \left\{ s \in E^* : s = s_a s_b, s_a \in L_a, s_b \in L_b \right\}$$

Prefix-closure of $L \subseteq E^*$:

$$\overline{L} := \left\{ s \in E^* : \exists_{t \in E^*} st \in L \right\}$$

Example 2.1 (Operations on languages)

[Cassandras99]

Let $E = \{a, b, g\}$, and consider the two languages $L_1 = \{\varepsilon, a, abb\}$ and $L_4 = \{g\}$.

Neither L_1 nor L_4 are prefix-closed, since $ab \notin L_1$ and $\varepsilon \notin L_4$. Then:

$$L_{1}L_{4} = \{g, ag, abbg\}$$

$$\overline{L_{1}} = \{\varepsilon, a, ab, abb\}$$

$$\overline{L_{4}} = \{\varepsilon, g\}$$

$$L_{1}\overline{L_{4}} = \{\varepsilon, a, abb, g, ag, abbg\}$$

$$L_{4}^{*} = \{\varepsilon, g, gg, ggg, \ldots\}$$

$$L_{1}^{*} = \{\varepsilon, a, abb, aa, aabb, abba, abbabb, \ldots\}$$

Automata Theory and Languages

Motivation: An *automaton* is a device capable of representing a language according to some rules.

Definition: A deterministic **automaton** is a 5-*tuple*

 (E, X, f, x_0, F)

where:

X

f

F

E	- finite alphabet (or possible events)
---	--

- finite set of states
- state transition function $f: X \times E \rightarrow X$

 $\mathbf{X}_0 \subset \mathbf{X}$

- **x**₀ initial state
 - set of final states or marked states $\mathbf{F} \subset \mathbf{E}$

[Cassandras93]

Word of caution: the word "state" is used here to mean "step" (Grafcet) or "place" (Petri Nets)

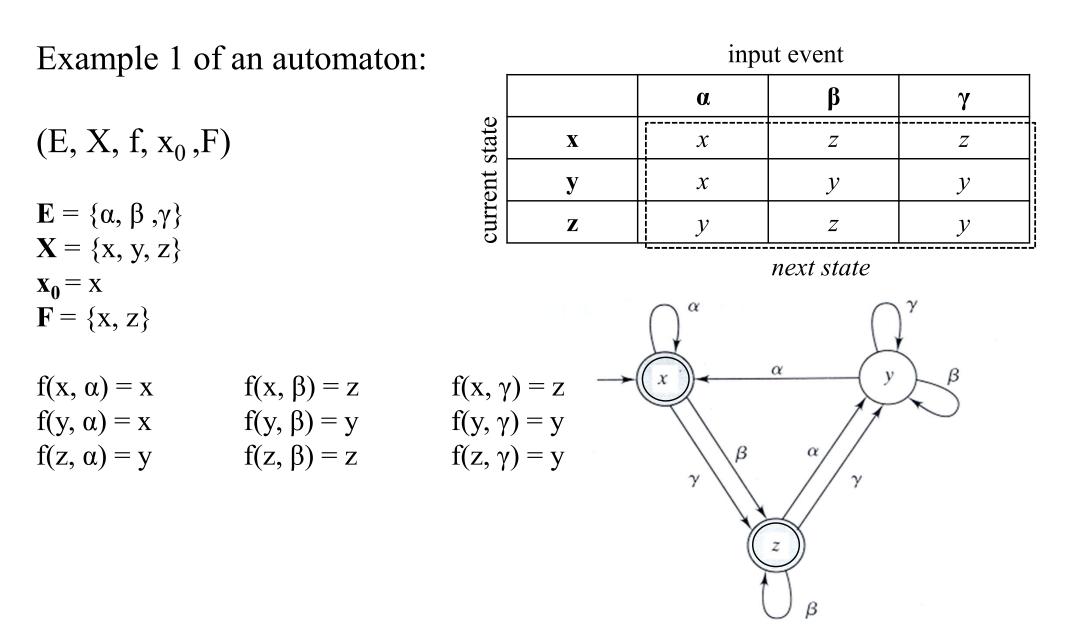

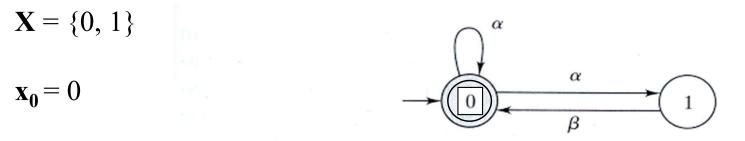

Figure 2.1. State transition diagram for Example 2.3.

Example 2 of a stochastic automaton

- (E, X, f, x_0, F)
- $\mathbf{E} = \{\alpha, \beta\}$

 $\mathbf{F} = \{0\}$ Figure 2.4. State transition diagram for the nondeterministic automaton of Example 2.7.

 $\begin{array}{ll} f(0,\,\alpha) = \{0,\,1\} & f(0,\,\beta) = \{\} \\ f(1,\,\alpha) = \{\} & f(1,\,\beta) = 0 \end{array}$

Given an automaton

$$G = (E, X, f, x_0, F)$$

the Generated Language is defined as

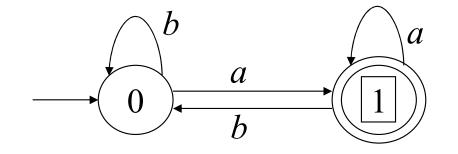

$L(G) := \{ s \in E^* : f(x_0, s) \text{ is defined} \}$

Note: if f is always defined for all events then $L(G) = =E^*$

and the Marked Language is defined as

$$L_m(G) := \{ s \in E^* : f(x_0, s) \in F \}$$

Example 3: marked language of an automaton

 $L(G) := \{\varepsilon, a, b, aa, ab, ba, bb, aaa, aab, baa, ...\}$

 $L_m(G) := \{a, aa, ba, aaa, baa, bba, \ldots\}$

Concluding, in this example $L_m(G)$ means all strings with events *a* and *b*, ended by event *a*.

Automata equivalence:

The automata $G_1 \in G_2$ are **equivalent** if

Example 4: two equivalent automata

Objective: To validate a sequence of events

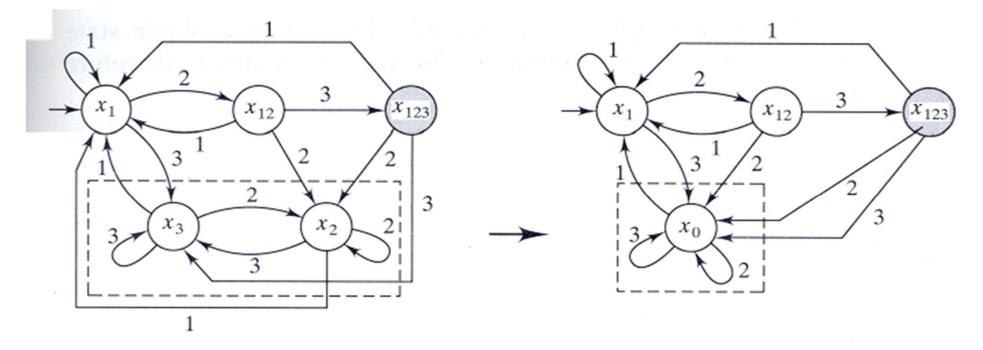

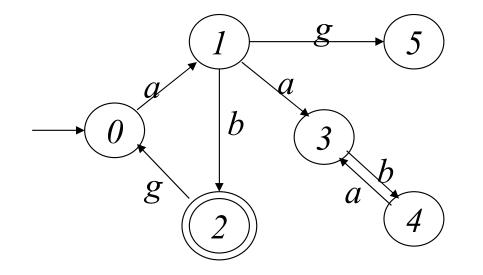

Figure 2.6. State transition diagrams for digit sequence detector in Example 2.9.

Deadlocks (*inter-blocagem*)

Example 5:

The state 5 is a *deadlock*.

The states *3* and *4* constitute a *livelock*.

How to find the *deadlocks* and the *livelocks*?

Need methodologies for the analysis of Discrete Event Systems Deadlock:

in general the following relations are verified

$$L_m(G) \subseteq \overline{L}_m(G) \subseteq L(G)$$

An automaton G has a **deadlock** if

$$\overline{L}_m(G) \subset L(G)$$

and is **not blocked** when

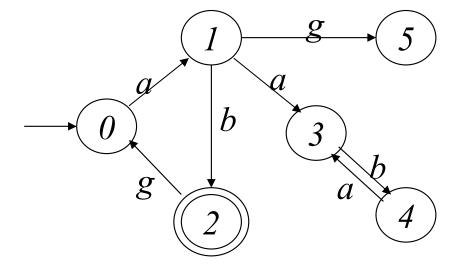

$$\overline{L}_m(G) = L(G)$$

Deadlock:

Example:

$$L_m(G) = \{ab, abgab, abgabgab, ...\}$$
$$L(G) = \{\varepsilon, a, ab, ag, aa, aab, \\abg, aaba, abga, ...\}$$

 $(L_m(G) \subset L(G))$

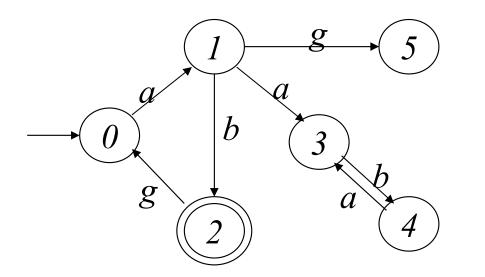

The state 5 is a *deadlock*.

The states *3* and *4* constitute a *livelock*.

 $\overline{L}_m(G) \neq L(G)$

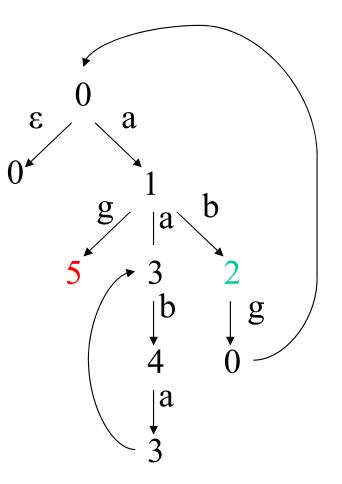

Alternative way to detect deadlocks:

Example:

The state 5 is a *deadlock*.

The states *3* and *4* constitute a *livelock*.

Timed Discrete Event Systems

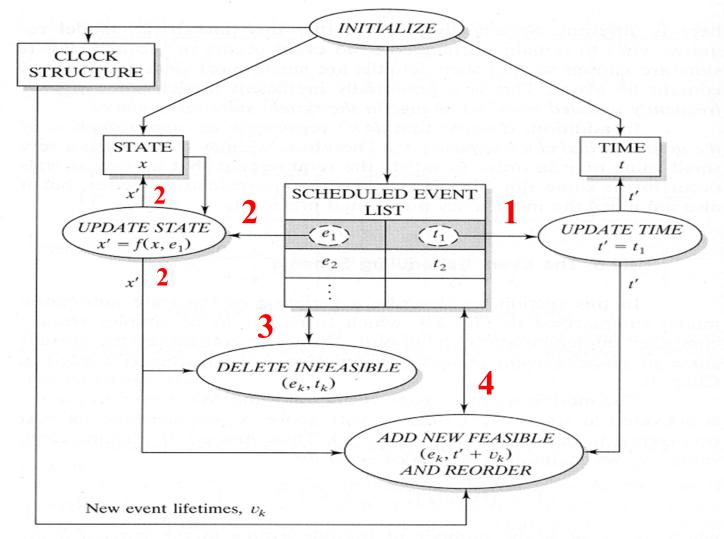

Figure 3.10. The event scheduling scheme.

Examples of Automata Classes and Applications

Automaton Class	Recognizable language	Applications	
Finite state machine (FSM), e.g. Moore machines or Mealy machines	Regular languages	Text processing, compilers, and hardware design	Very small memory (just the state / number of states)
Pushdown automaton (PDA)	Context-free languages	Programming languages, artificial intelligence, (originally) study of the human languages	Memory : ∞ Stack
Turing machine (nondeterministic, deterministic, multitape,)	Recursively enumerable languages	Theory, complexity	Memory : ∞ Tape

Another development direction: parallelism (next slides)

Petri nets Developed by Carl Adam Petri in his PhD thesis in 1962.

Definition #1 (of 3 alternatives) [Cassandras08, §2.2.4]:

A marked Petri net is a 5-tuple

 (P, T, A, w, x_0)

where:

Ρ

- set of places
- T set of transitions
- A set of arcs
- w weight function
- **x**₀ initial marking

 $A \subset (P \times T) \cup (T \times P)$ $w: A \to N$ $x_0: P \to N$

Example of a Petri net

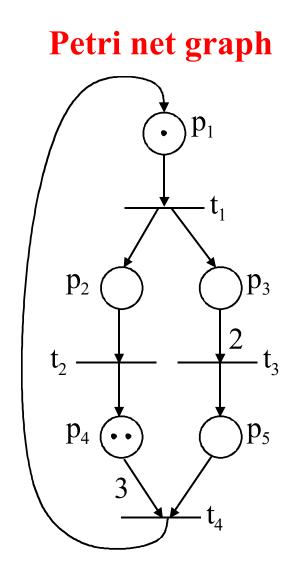

- (P, T, A, w, x_0)
- $P{=}\{p_1,\,p_2,\,p_3,\,p_4,\,p_5\}$

 $T = \{t_1, t_2, t_3, t_4\}$

 $A = \{(p_1, t_1), (t_1, p_2), (t_1, p_3), (p_2, t_2), (p_3, t_3), (t_2, p_4), (t_3, p_5), (p_4, t_4), (p_5, t_4), (t_4, p_1)\}$

 $w(p_1, t_1)=1, w(t_1, p_2)=1, w(t_1, p_3)=1, w(p_2, t_2)=1$ $w(p_3, t_3)=2, w(t_2, p_4)=1, w(t_3, p_5)=1, w(p_4, t_4)=3$ $w(p_5, t_4)=1, w(t_4, p_1)=1$

 $\mathbf{x}_0 = \{1, 0, 0, 2, 0\}$

Petri nets

Rules to follow to create a Petri net:

- Arcs indicate directed connections connect places to transitions and connect transitions to places
- A transition can have no places directly as inputs (source), *i.e. must exist arcs between transitions and places*A transition can have no places directly as outputs (sink), *i.e. must exist arcs between transitions and places*
- The same happens with the input and output transitions for places

Alternative definition of a Petri net (#2 of 3 alternatives)

A marked Petri net is a *5-tuple* [Peterson81]

(**P**, **T**, **I**, **O**, μ_0)

where:

 $\begin{array}{lll} P & - \mbox{ set of places} \\ T & - \mbox{ set of transitions} \\ I & - \mbox{ transition input function} & I: \ T \rightarrow P^\infty \\ O & - \mbox{ transition output function} & O: \ T \rightarrow P^\infty \\ \mu_0 & - \mbox{ initial marking} & \mu_0: \ P \rightarrow N \end{array}$

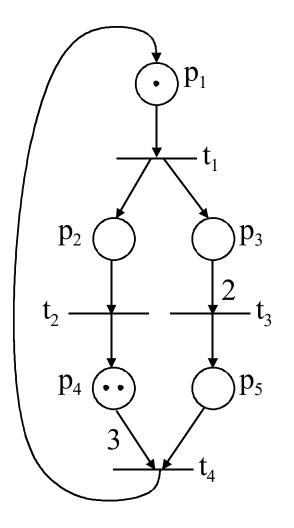

Note: $\mathbf{P}^{\infty} =$ bag of places (is more general than a set of places)

Example of a Petri net and its graphical representation

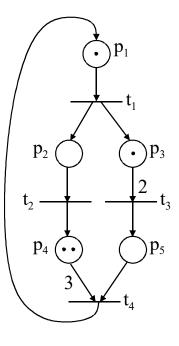

Alternative definition

 $\begin{array}{ll} (P, T, I, O, \mu_0) \\ P = \{p_1, p_2, p_3, p_4, p_5\} \\ T = \{t_1, t_2, t_3, t_4\} \\ I(t_1) = \{p_1\} & O(t_1) = \{p_2, p_3\} \\ I(t_2) = \{p_2\} & O(t_2) = \{p_4\} \\ I(t_3) = \{p_3, p_3\} & O(t_3) = \{p_5\} \\ I(t_4) = \{p_4, p_4, p_4, p_5\} & O(t_4) = \{p_1\} \end{array}$

 $\mu_0 = \{1, 0, 0, 2, 0\}$

Petri nets: State, Markings, Weights of Arcs

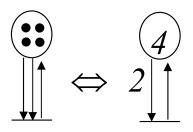

- The state of a Petri net is characterized by the marking of all places $\mu = (\mu_{p1}, \mu_{p2}, \mu_{p3}, \mu_{p4}, \mu_{p5})$
- The set of all possible markings of a Petri net corresponds to its **state space**:

 $\{(1,0,1,2,0), (0,1,2,2,0), (0,0,0,3,1), (1,0,0,0,0)\}$

How does the state of a Petri net evolve?

Simplifying notation of markings and cardinality (weight) of the arcs:

Formal nomenclature:

$$p_{i} \qquad n = \#(p_{i}, I(t_{j}))$$

$$n \qquad m = \#(p_{i}, O(t_{j}))$$

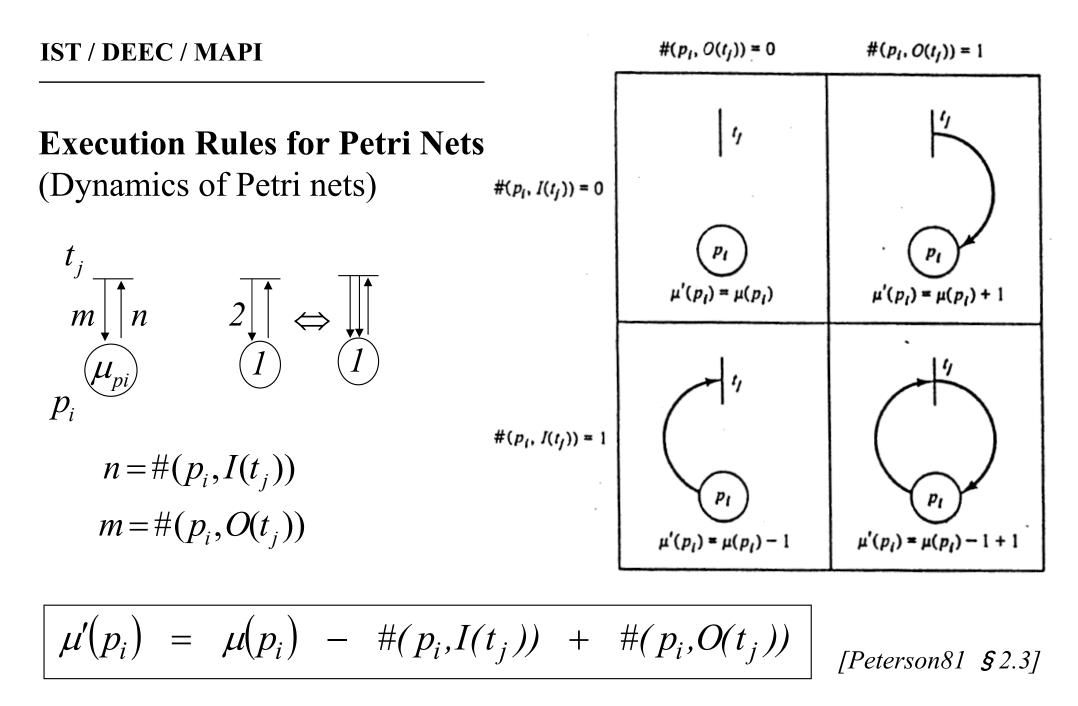

$$t_{j} \qquad m = \#(p_{i}, O(t_{j}))$$

Execution Rules for Petri Nets (Dynamics of Petri nets)

A transition
$$t_j \in T$$
 is *enabled* if:
 $\forall p_i \in P$: $\mu(p_i) \geq \#(p_i, I(t_j))$
A transition $t_j \in T$ may *fire* whenever enabled, resulting in a new marking given by:
 $\mu'(p_i) = \mu(p_i) - \#(p_i, I(t_j)) + \#(p_i, O(t_j))$

 $#(p_i, I(t_j)) = multiplicity of the arc from p_i to t_j$ $#(p_i, O(t_j)) = multiplicity of the arc from t_j to p_i$ [Peterson81 § 2.3]

Page 34

Later this dynamic equation will be generalized using vector notation $\mu_{k+1} = \mu_k + (D^+ - D^-)q_k$

Page 35

Petri nets

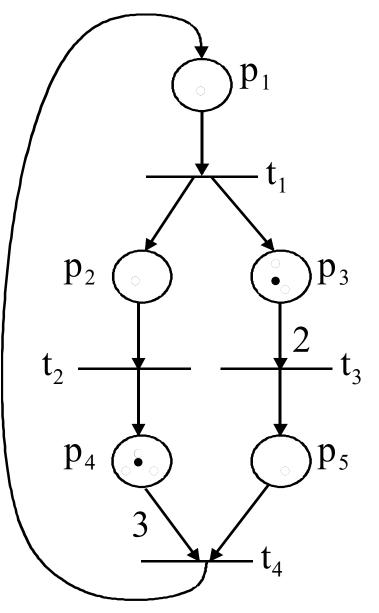

Example of evolution of a Petri net

Initial marking:

 $\mu_0 = \{1, 0, 1, 2, 0\}$

This discrete event system can not change state.

It is in a *deadlock!*

Petri nets: Conditions and Events (Places and Transitions)

Example: Machine waits until an order appears and then machines the ordered part and sends it out for delivery.

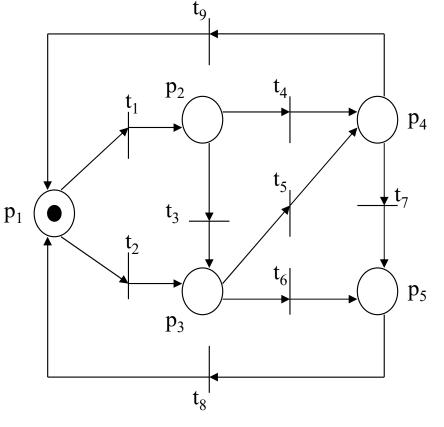

Conditions: The server is idle. Event Posa) Pre-A job arrives and waits to be processed **b**) conditions conditions The server is processing the job c) b The job is complete **d**) 2 **Events** a, b С Job arrival 1) 3 d, a С 2) Server starts processing 3) Server finishes processing 4 d The job is delivered 4) a) Server is idle c) Job is being d) Job is b) Jobs waits processing processed complete 2) Start of 3) End of 4) Job is 1) Job arrival processing processing delivered Page 37

Discrete Event Systems

Example of a simple automation system modeled using PNs

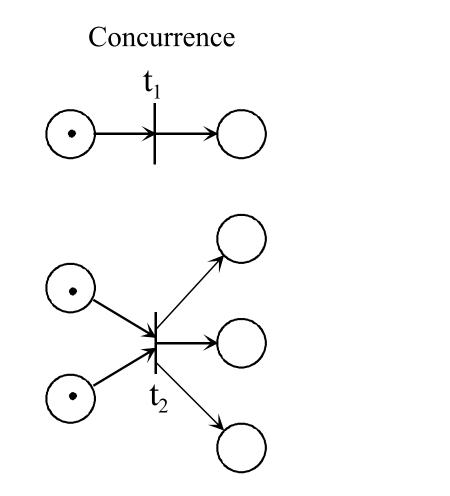

An automatic soda selling machine accepts 50c and \$1 coins and sells 2 types of products: SODA A, that costs \$1.50 and SODA B, that costs \$2.00.

Assume that the money return operation is omitted.

 $p_1: \text{ machine with $0.00;} \\ t_1, t_3, t_5, t_7: \text{ coin of 50 c introduced;} \\ t_2, t_4, t_6: \text{ coin of $1 introduced;} \\ t_9: \text{ SODA A sold, } t_8: \text{ SODA B sold.} \\ \text{Page 38}$

Discrete Event Systems Sub-classes of Petri nets

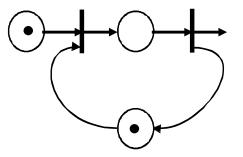

State Machine:

Petri nets where each transition has exactly one input arc and one output arc.

Marked Graphs:

Petri nets where each place has lesser than or equal to one input arc and one output arc.

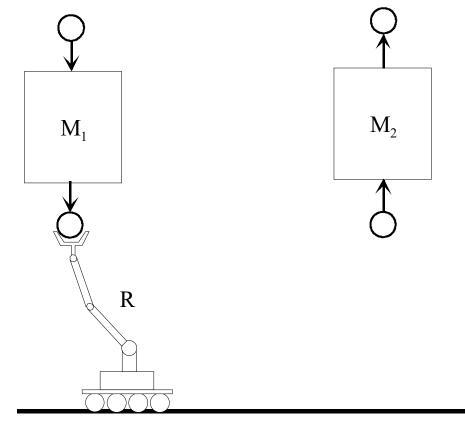

Discrete Event Systems Example of DES:

Manufacturing system composed by **2 machines** (M_1 and M_2) and a robotic **manipulator** (R). This takes the finished parts from machine M_1 and transports them to M_2 .

No buffers available on the machines. If R arrives near M_1 and the machine is busy, the part is rejected.

If R arrives near M_2 and the machine is busy, the manipulator must wait.

Machining time: $M_1=0.5s$ $R_{M1 \rightarrow M2}=0.2s$ $M_2=1.5s$ $R_{M2 \rightarrow M1}=0.1s$

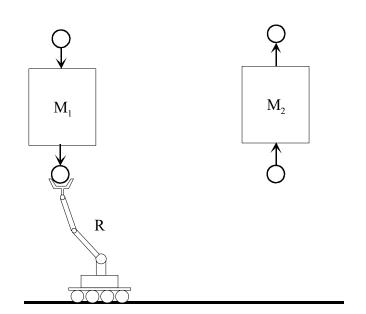

Discrete Event Systems Example of DES:

Define places

- $M_1 \qquad \text{is characterized by places} \\ x_1 = \{\text{Idle, Busy, Waiting}\}$
- $M_2 \qquad \mbox{is characterized by places} \\ x_2 = \{ \mbox{Idle, Busy} \}$
- R is characterized by places $x_3 = \{Idle, Carrying, Returning\}$

Example of arrival of parts:

$$a(t) = \begin{cases} 1 & in \quad \{0.1, \quad 0.7, \quad 1.1, \quad 1.6, \quad 2.5\} \\ 0 & in & other \ time \ stamps \end{cases}$$

Discrete Event Systems Example of DES:

Definition of events:

 \mathbf{r}_1

 \mathbf{r}_2

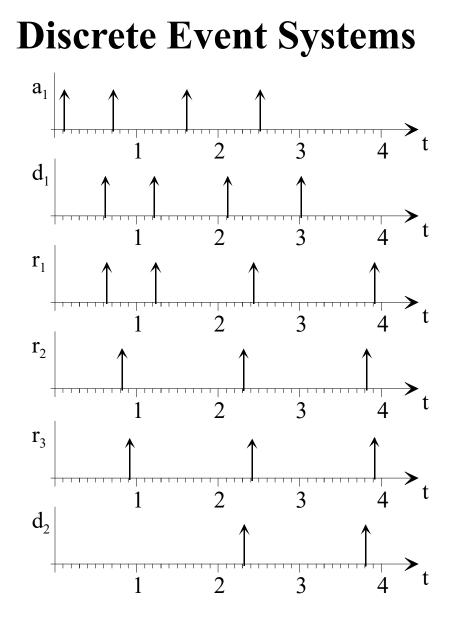

a ₁	- loads part in M_1
d_1	- ends part processing in M_1

loads manipulator
unloads manipulator and

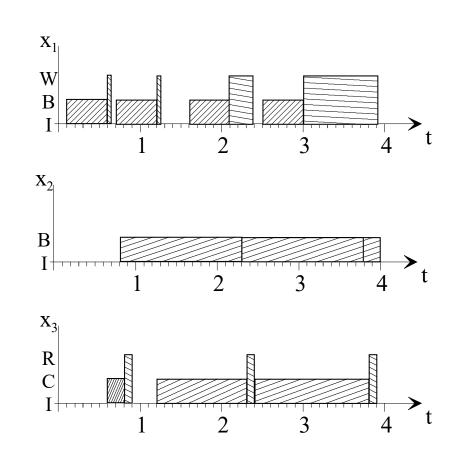

loads M₂

d₂ - ends part processing in M₂
r₃ - manipulator at base

 $x_1 = \{Idle, Busy, Waiting\}$ $x_2 = \{Idle, Busy\}$ $x_3 = \{Idle, Carrying, Returning\}$

Discrete Event Systems

Example of DES:

Events:

 a_1 - loads part in M_1 d_1 - ends part processing in M_1 r₁- loads manipulator r₂- unloads manipulator and loads M₂ d₂- ends part processing in M₂ r_3 - manipulator at base
